- Question 1: Many factors influence students' preference for off-print vs e-assessments. For example, some students prefer e-assessments because they allow for using notes (sometimes) and provide quick feedback. In contrast, others prefer off-print assessments because they feel more legitimate and eliminate issues with cheating and technology. Additionally, some students may find that e-assessments are less stressful and more convenient, while others feel that off-print exams are better for assessing understanding and avoiding mistakes. Ultimately, the choice between e-assessments and off-print assessments may depend on the specific exam and the test taker's individual preferences and circumstances.
- Question 2: There are various reasons why students might prefer to have more e-assessments in the future, including convenience, reduced stress, accessibility, and faster feedback. However, concerns about cheating, the fairness of the exams, and technical issues may arise. Therefore, balancing these factors is essential to increase the number of e-assessments in the future.
- Question 3: Based on the student responses, students have varied opinions on the effectiveness of e-assessments in accurately reflecting their understanding of course material. Some students feel that e-assessments are a better way to test their understanding of the material since they focus on application rather than memorization. In addition, they think these e-assessments are often open-book exams, allowing for a clearer thought process. In contrast, other students feel that e-assessments have poor question format and do not provide credit for workings, which can negatively impact their grades and understanding. Overall, students have different experiences with e-assessments and the effectiveness of e-assessments in accurately reflecting student understanding of the course material depends on various factors such as question format, time constraints, and personal preferences.
- Question 4: Based on the student responses, most students find e-assessment exams helpful for getting quick feedback on their performance. They appreciate seeing where they made mistakes and what areas to improve. However, some students feel that the feedback is too minimal and that more explanation would be helpful, especially for more complicated questions. The difference in question style between mid-term exams and end-of-year assessments was also noted as a potential limitation. Additionally, some students feel that not enough feedback is given by their professors for the end-of-term off-print exams, so the e-assessment midterm exams provide valuable feedback.

5 Conclusion

The quick feedback provided by electronic assessments is generally seen as beneficial for students to gauge their learning and improve. However, there may be some concerns about the accuracy of electronic assessments in reflecting students' understanding of course material. Providing more explanation and feedback for complicated questions in electronic assessments may help students better understand their performance and improve their learning. Based on the results, most student participants prefer e-assessments and would be willing to take more electronic exams in the future. Their choice is mostly based on the quick feedback they get. In addition, most teachers are also opting for e-assessments due to the flexibility in assessment design and a reduced marking workload.

Overall, the results suggest that electronic assessments have benefits, but some limitations must be addressed. Further research could investigate ways to improve the accuracy of electronic assessments and address concerns about cheating, fairness, and technical issues. At the moment, the choice between off-print and electronic assessments may depend on the specific exam and the individual preferences and circumstances of the test taker, but surely, with the development of assessment software, e-assessments will completely replace paper-based examinations as they are prefered both by students and staff for different reasons discussed in this paper.

ABSTRACT

This practice paper explores the impact of effective digitised feedback on engineering students' mathematics learning in the digital environment. By using a schematic framework, an online repository will be developed to provide effective feedback to the first-year students taking mathematics courses. The repository takes into account calculus topics and focuses on providing guidance to students who give incorrect answers to questions by incorporating sub-questions based on Polya's heuristics. The sub-questions aim to motivate students to draw on simpler connections and stimulate learning by encouraging students to check their answers and reflect on their initial responses. This study is currently an ongoing project in the Netherlands and aims to improve outcomes in calculus courses and provide a database of online exercises for digital exams, which will save teachers time, in long term.

1 INTRODUCTION

In recent years, the integration of technology into education has become increasingly prevalent, transforming traditional learning environments and offering new opportunities for innovative instructional approaches. Engineering education, in particular, has witnessed the incorporation of digital tools and platforms to enhance the teaching and learning process. Within this context, the focus on mathematics learning and the provision of feedback have emerged as critical areas of investigation. By leveraging the potential of digital platforms, this study aims to enhance the effectiveness and engagement of students in their mathematical studies.

Recent advancements in educational technology have paved the way for the development of digitised effective feedback systems that go beyond conventional feedback mechanisms. The MAA National Study of College Calculus conducted by Bressoud, Mesa, and Rasmussen (2015) provides valuable insights and recommendations for implementing effective feedback strategies in college-level calculus courses. Their findings emphasise the importance of timely and constructive feedback in enhancing student learning outcomes.

In addition to the cognitive aspects of learning, the effective dimensions, including students' emotions and engagement, play a crucial role in the learning process. Research by Pekrun, Goetz, Titz, and Perry (2002) and Fredricks, Blumenfeld, and Paris (2004) explores the influence of effective feedback on students' self-regulated learning and engagement. Understanding and addressing students' effective experiences through digitised feedback can contribute to creating a supportive and motivating learning environment.

To guide students in their problem-solving processes, this study also draws upon the principles of Polya's problem-solving heuristics. Kilpatrick, Swafford, and Findell (2001) discuss the importance of problem-solving skills and approaches in mathematics education in their influential book "Adding It Up: Helping Children Learn Mathematics." By incorporating Polya's problem-solving heuristics, educators can empower students to develop essential problem-solving skills, fostering a deeper understanding of mathematics.

In conclusion, this paper addresses the pressing need to explore the potential of digitised effective feedback in mathematics learning within the context of engineering education. By building upon existing scholarship, including recent advancements, key papers, and notable research, and leveraging theoretical frameworks, the study aims to contribute to the field's knowledge base. The findings of this research will inform the development of an online repository of questions and exercises that integrate effective feedback, offering valuable resources to the SEFI community and advancing the learning experiences of engineering students in mathematics courses.

1.1 Research Question

Based on the above considerations and the need to enhance mathematics learning in engineering education, this study aims to investigate the impact of effective digitised feedback, incorporating sub-questions based on Polya's heuristics, on engineering students' mathematics learning in the digital environment. Therefore, the main research question is: What is the impact of effective digitised feedback on engineering students' mathematics learning and problem-solving abilities? To address this question comprehensively, this paper will undertake an exploration of the subsequent inquiries: How do these sub-questions based on Polya's heuristics contribute to the resolution of the main problem, and in what ways can their efficacy be further enhanced? Interviews were conducted with two first-year students, denoted as a student with intermediate proficiency (SIP) and a student with low proficiency (SLP), whose feedback has been presented in the results section of this paper.

2 METHODOLOGY

Since 2020, the University of Twente (UTwente) has been utilizing the Grasple online learning platform[1], which offers hint-based feedback to students through exercises sourced from other technical universities in the Netherlands. Course evaluations have consistently indicated that students are highly satisfied with the use of this online platform. However, there is a pressing need to enhance the exercises available in the Grasple repository to align them more closely with the specific learning objectives of UT's Mathline courses.

The aforementioned repository takes into consideration calculus topics, such as vectors, limits, and derivatives, which are part of an ongoing project called the 4TU Teaching and Learning Fellowship at UTwente. The aim of this project is to develop constructive feedback mechanisms for students by improving the existing repository of questions and creating new ones. The main focus is on providing sub-questions that can guide students who have given incorrect answers, serving as stepping stones to help them overcome challenges in problem-solving. These sub-questions are developed by the researcher based on relevant literature and their own teaching experience.

To guide the development of sub-questions, the framework of Polya's heuristics (1957) and Schoenfeld's metacognitive aspects of successful problem-solving (1985) are taken into account. Polya's heuristics emphasise understanding the problem, devising a plan, executing the plan, and reflecting on the solution as key steps in effective problem-solving. The heuristics offer students systematic approaches, such as working backward, drawing diagrams, making assumptions, and considering special cases, to enhance their problem-solving skills.

In Figure 1, an example from Grasple is presented, focusing on the creation of a plane equation using given vectors. The hint-based feedback is provided to students when they answer the question incorrectly, aiming to facilitate their learning process. Inspired by Schoenfeld (1985), the strategy of solving an easier, related problem first is employed as a means to support students in tackling the original problem. The sub-questions act as stepping stones and encompass concepts such as the dot product, vector construction, and visualizing components.

Another important aspect in problem-solving, as advocated by Polya, is the step of looking back. This encourages students to review their answers, analyzing them for accuracy and reasonableness. It also provides an opportunity for students to reflect on their initial responses and approach the problem with a more conscious consideration. This step will be integrated at the end of the sub-questions to further

[1] Grasple. "Homepage." Grasple. https://www.grasple.com/.

support students' learning process. Table 1 provides an overview of the sub-questions based on the guide to problem-solving techniques outlined in Polya's work (1957).

By incorporating these research-based strategies, our objective is to enhance students' mathematical learning experiences and improve their problem-solving abilities within the Grasple platform. To measure the effectiveness of our approach, we will interview a larger sample of engineering students after introducing the sub-questions in their studies. Additionally, we will compare the passing rates with the previous year's data. This expanded sample will provide valuable insights into the impact of effective digitised feedback on their mathematics learning and problem-solving abilities. Through the development of effective sub-questions and the integration of Polya's heuristics and Schoenfeld's metacognitive aspects, we anticipate creating a more comprehensive and engaging learning environment that fosters students' growth and success.

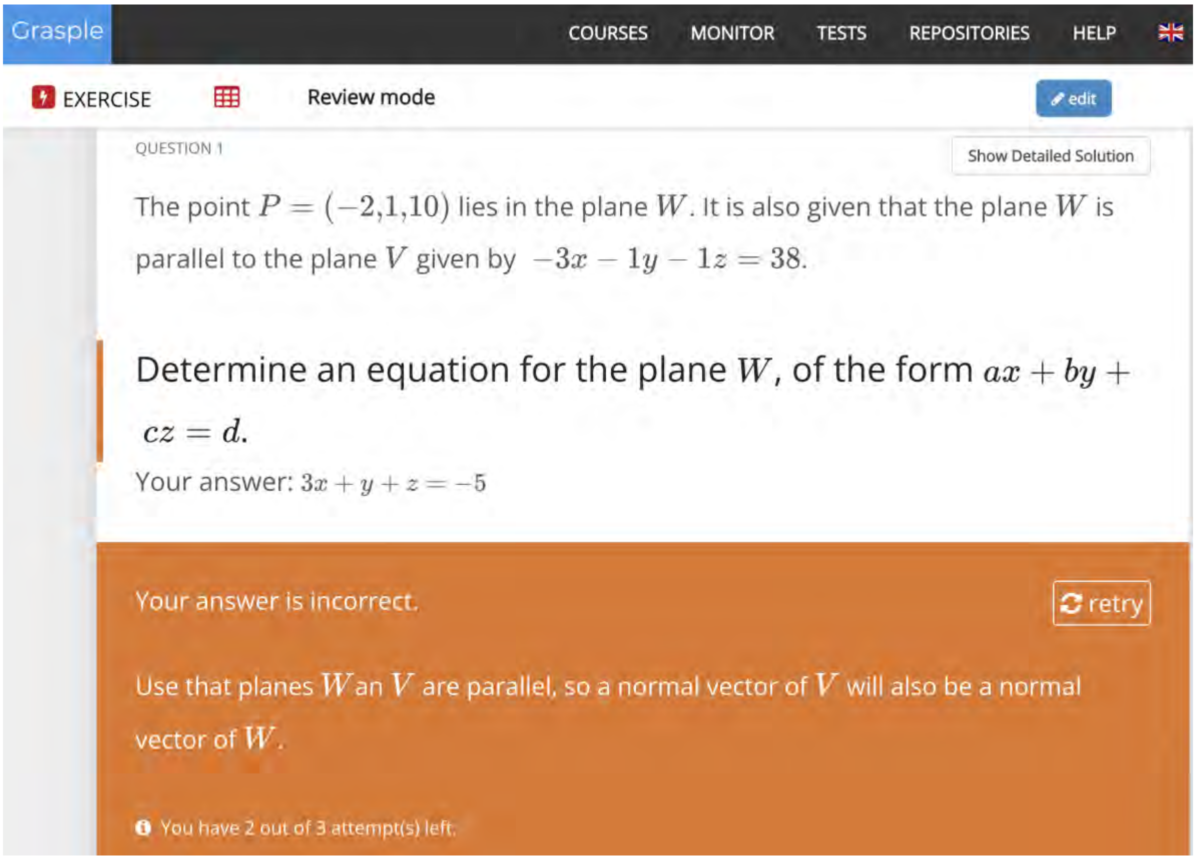

Fig. 1. The original final answer question with a hint due to incorrect answer on Grasple.

Table 1. The sub-questions by using the guide to problem-solving techniques (Polya 1957).

Phases	The sub-questions with Heuristic Approaches
1. **<u>Understanding the problem:</u>** Polya emphasises the significance of understanding the problem before attempting to solve it. This involves reading the problem carefully, identifying the given information, and clarifying the desired outcome.	**Sub-question 1: Understanding the given information (Relating Planes):** Before tackling the original problem, it is essential to determine the given information. The final answer sub-questions could be: • Which point lies in the plane W? • Which equation represents the plane V that is parallel to the plane W?
2. **<u>Devising a plan:</u>** Polya highlights the importance of devising a plan or strategy for solving the problem. This involves breaking down the problem into smaller, more manageable parts, recognizing patterns or similarities to previously solved problems, and considering alternative approaches.	**Sub-question 2: Determine the normal vector of plane V:** Understanding the concept of a normal vector and its relation to a plane equation is essential for solving the original problem. This sub-question helps reinforce the connection between normal vectors and plane equations. The sub-questions could be: • Which vector is perpendicular to the plane V? a) (-3,1,1) b) (0,-1,1) c) (-3,-1,-1) d) (1,0,-3) **Sub-question 3: Visualizing the components:** Visualise the components of the vectors and their relationship in three-dimensional space. This step helps in understanding the geometric interpretation of the plane equation.The sub-question could be: • Which of the following statements is true about the two parallel planes? a) Their respective normal vectors are parallel. b) Their respective normal vectors are perpendicular.

	Sub-question 4: Identify the relationship between parallel planes: Understanding the relationship between parallel planes is crucial for solving the original problem. By exploring this sub-question, the student will develop a deeper understanding of how parallel planes are related in terms of their normal vectors and equations. The sub-question could be: • Determine the normal vector of the plane W. a) (0,-1,1) b) (-3,-1,-1) c) (1,0,-3) d) (-3,1,1)
3. <u>Carrying out the plan:</u> Once a plan is formulated, Polya advises students to execute it step by step, applying appropriate mathematical concepts and techniques. He encourages students to be flexible and willing to revise their plan if necessary.	**Sub-question 5: Dot product calculation:** Calculate the dot product of the constructed vectors. The dot product is a crucial operation when working with vectors and plays a big role in defining planes.The sub-question could be: • Using the point P=(-2, 1, 10) and the normal vector of the plane W, determine the equation of the plane W. a) 2x-y-10=38 b) -3x-y-z=-5 c) -2x+y+10=38 d) 3x+y+z=-5
4. <u>Looking back:</u> After obtaining a solution, Polya suggests reflecting on the problem-solving process. This includes verifying the solution's accuracy, assessing the reasonableness of the answer, and considering alternative methods or perspectives.	**Sub-question 6: Reflecting on the solution:** This question prompts the student to substitute the coordinates of point P into the equation of plane W and determine if the equation holds true for the given point, without explicitly providing the direction (positive or negative) of the statement. The sub-question could be: • Verify if the point P=(-2, 1, 10) lies on the plane W represented by the equation ax + by + cz = d.

		a) Yes, the point P lies on the plane W. b) No, the point P does not lie on the plane W.

3 RESULTS AND DISCUSSIONS

In the following section, we will present the outcomes based on our interpretation of the extracts obtained from the conducted interviews. Each interview lasted approximately 45 minutes and was recorded for accurate documentation. The Grasple question depicted in Figure 1 was given to two first-year engineering students at UTwente: a student with intermediate proficiency (SIP) and a student with low proficiency (SLP). Initially, both students encountered difficulties in solving the main problem. However, upon the introduction of the sub-questions aligned with Polya's heuristics, both students successfully arrived at the correct answer. The interview encompassed a concise set of approximately two questions, namely: (1) How do these sub-questions based on Polya's heuristics contribute to the resolution of the main problem? and (2) In what ways can their efficacy be further enhanced?

<u>(1) How do these sub-questions based on Polya's heuristics contribute to the resolution of the main problem?</u>

- Overall: "*I would say in general it was a lot better than the Grasple right now. Because I know a lot of people are getting frustrated when they make a small mistake or a big mistake, whatever, and then it just says you're wrong and the explanation is not super clear. Or for example, the explanation assumes that you know something and just skips that part […] and some people just I know what we're trying to just learn how to solve what Grasple wants you to solve and that didn't seem right, but this seems a lot better […] it's like takes your hand and just follows you through the whole thing." (SIP). "I like them, because you could see it [the solution] step by step."(SLP).*

- Regarding the first phase: *"People make a lot of mistakes when reading and a lot of times you fail to solve for Grasple because you just didn't finish the sentence because you know you already know what's gonna be there. But it's not there."(SIP). "Well, these are mostly the questions that I ask myself first, so I write them down first of all.[…] That's the basic step to start any question, just write everything down that's asked from the question itself."(SLP).*

- Regarding phases 2 and 3: *"I think you can definitely see the correlation to the original equation. So we should be able to make the connection."(SIP). "So it's a good continuation on your thought process about entering question 4 from question 2." (SLP).*

- Regarding the last question: *"I like the last question because it forces you to double check your work, which people always not do, and it's a good habit to force people to do it and maybe they will actually end up doing it in their life. So* *that's nice." (SIP). "It's a nice finisher, because then you can see, OK, the point P does fit into the correct formula which you answered and if I answered [question] 5 incorrectly, then it wouldn't work."(SLP).*

(2) In what ways can their efficacy be further enhanced?

- Point of improvement: *"Maybe not these questions themselves, but like if the question is way more complex and if a person does not know the theory and he gets more like he tries, it gets wrong. Maybe it's great if it would kind of give you a short theory where referring to for example. it would be nice if it, like gives you that, but only if it's like a complicated thing […] So you make a mistake, right? You double check your work and then you saw correctly. Then you don't need the theory. But if you make two mistakes in a row, I guess then it's nice for you to get the theory." (SIP). "[In Phase 2] I would like to see some theory about it, and maybe a 3D visualisation on why the numbers are connected. […] Yes, for me it's clear, but I made a 3D visualisation in my head where I had two planes and if you have two perpendicular vectors, one from the plane downwards up or one from the plane. They [normal vectors] are parallel."(SLP).*

Based on the students' feedback, we discern a positive interpretation, highlighting the advantages associated with the implementation of the sub-questions. The interview outcomes reveal that both phase 1, involving the understanding of the given information, and phase 4, related to the reflection on the solution, play significant roles as essential stages in assisting students in resolving the main problem. In light of this feedback, we are committed to diligently considering their recommendations for enhancing the project.

This study is anticipated to yield substantial improvements in outcomes for calculus courses, which are essential components of various study programs at the University of Twente. Additionally, it aims to establish a comprehensive database of online exercises that can be utilized for digital exams, resulting in considerable time savings for teachers. The project's timeline indicates that the outcomes for larger interview sample will be available by the end of the first quarter of the upcoming academic year allowing us to address our main research question. This project introduces a practical and innovative approach to providing effective feedback to engineering students, thereby significantly enhancing their learning experience and preparing them for the challenges of a complex and sustainable world. Further research has been conducted, and additional examples will be presented and discussed during the Poster presentation of this study at SEFI 2023.

4 ACKNOWLEDGMENTS

This research was made possible thanks to funding, input and feedback from the 4TU CEE organization in The Netherlands. We gratefully acknowledge Tracy Craig for her invaluable feedback to this practice paper.

ABSTRACT

Digital reality has been gradually introduced into all parts of human society, and the field of education is no exception due to the potential of technology and related tools to enhance the teaching and learning process. However, there is still a paucity of research in this area within an Irish higher education context.
The research explores how to best employ virtual reality (VR), using the Oculus Quest 2 system, to improve and develop the level of contemporary training, as well as to enhance the educational experience. Both the technical and educational perspectives will be considered.
The researched sample consists of 25 undergraduate students representing different profiles from within engineering education. The data collection included two stages, namely written questionnaires, and short semi-structured interviews relating to training sessions with Oculus Quest 2, in which participants were exposed to life on board the International Space Station (ISS), including the experiments and missions performed on the station.
The results of the short interviews and questionnaires extracted in this work reflected that all the participants were very excited to work and interact with the experiences of virtual reality in engineering education. In addition, they rated the usability of virtual

[1] *Corresponding Author: H. Al-Juboori, e-mail: haider.aljuboori@setu.ie*

reality glasses overall as being very satisfactory, despite some students expressing the presence of minor challenges or problems.
Most of the participants' reactions were positive regarding the possibility of including virtual reality devices and associated technologies in future training and support, as they indicated that these training sessions increased their motivation and passion for learning, whilst at the same time, supported the development of their digital reality skills.. In general, the outputs of the research show that the inclusion and empowerment of digital reality within higher education programmes can have significant value and benefit, leading to the recommendation that it would be used more extensively in the future.

1 INTRODUCTION

Digital tools based on virtual reality (VR) technologies have witnessed a remarkable expansion in recent times, especially with the increase in features and characteristics available and their relative ease of use. The popularity of these technologies has increased rapidly in the field of games platforms, in addition to gaining traction within the fields of education and health care training (W. Werner et al. 2007 and R. Jaziar et al. 2020). Additionally, its unique features, such as the sense of presence and the immersive experience of losing connection to the physical world, have led to creating new interest for users (R. Jaziar et al. 2020 and W. Peng 2018).
It is worth noting that the non-prohibitive cost of such technologies has allowed researchers to use and work on developing specific applications suitable for use in academic environments (Y. Zinchenko et al. 2020 and D. Carruth 2017). In addition, these technologies represent a good alternative or complementary solution for some complex, sensitive and expensive engineering devices and laboratories (Z. Zacharias et al. 2014, K. Winkelmann et al. 2020 and G. Mosquera et al. 2018).
This research work presents the means by which the VR equipment (i.e., the Oculus Quest 2 system consisting of a VR headset (head-mounted display) and two controllers) was used as a support tool in engineering education to enhance the current learning approach. Also, the work focuses on how to incorporate learning theories during the selection or design of virtual reality (VR) applications. Equally, this would allow for the development of a general framework for building, managing, examining and evaluating VR technologies that are designed within specific areas of engineering education.
The promising results of this work may open creative ideas towards establishing the technical and educational foundations for remote learning, which provides an opportunity for higher education institutions (HEIs) to engage in knowledge sharing and co-creation on an international basis.
In that respect, there are potential benefits from an educational perspective of integrating virtual reality technologies into the curricula. In terms of context, the current work sheds light on the benefits and challenges that the students faced during training sessions, as a case study in the Faculty of Engineering, South East Technological University (SETU), Carlow, in Ireland.
The work will focus on addressing the following sub-questions in the context of the current work under the project name “CarlowENG-VR1.0”:

1- From the perspective of the students, what is the effect of using virtual reality on their motivation and engagement?
2- In terms of educational setting and preparations, what should be considered when developing educational programmes that employ virtual reality?

3- What are the additional and unique features that VR environments offer in terms of pedagogical ?
4- How will the VR headsets (i.e., head-mounted display "HMDs" combined with multi-axis inertial measurement unit "IMUs") support the learning process and the development of attendant exploratory skills, from the perspective of the students?

In the next section. the project details and selected results will be presented, based on the experience gained, and the possibilities to employ a suitable digital reality system will be explored.

2 MATERIALS AND METHODS

2.1 Participants: Undergraduate Students

Undergraduate students from a range of engineering-related programmes, inter alia, electronics, and aerospace engineering, were notified regarding this project and were invited to participate on a voluntary basis. The invite was circulated to a total of 35 students, of which 25 opted to be involved and we can be confirming that informed consent was obtained from all 25 participants for these experiments. SETU Carlow Research Ethics Committee confirmed this project is compliant with statutory requirements and is conducted to the highest ethical principles.

2.2 Research Design

Each student who participated received project information and data collection debriefing over a number of days, in the second semester of the academic year 2022-2023. Each session lasted approximately 30 minutes and included the following activities:

1- An initial project information session by means of a short PowerPoint presentation (approximately 5 mins);
2- An initial individual, paper-based survey that had to be completed by each participant before using an immersive VR training session – survey completion time (5-7 mins);
3- A demonstration of the handling of the VR equipment (5 mins),
4- Individual guidance with the VR equipment according to the required training task (10-15 mins); and
5- A second individual, paper-based survey and a short interview with each participant (5-10 mins).

2.3 Contents and Framework of the Training Session

There are several educational perspectives that can be considered in engineering education and in this context, the chosen topic of the training session was selected based on the following two criteria:

(1) It should be of interest to prospective engineering students; and
(2) It should be based on digital reality (i.e., VR tools), in that it should have the ability to add notable and value, in terms of simplifying the contents and being more flexible and accessible than traditional teaching methods.

To match the students' profiles, which included electronics and avionics engineering majors, the chosen topic centred on the experiments and mission exploration being performed on the International Space Station. This was seen as a suitable case study which could provide new information, knowledge and skills.

It is worth mentioning, that NASA uses these technologies for training purposes in their own Virtual Reality Laboratory (VRL), which is an immersive training facility providing

real-time graphics and motion simulators, integrated with a tendon-driven robotic device. This provides the kinaesthetic sensation of the mass and inertia characteristics of any large object (around 500lb or 226 kg) being handled (A. Guzman 2022), as shown in Figure 1a.
In all of the educational experiments conducted as part of this study, the Oculus Quest 2 system was used, which itself is a rather recent technical development. It was introduced to the markets as Meta Quest 2 at the end of November 2021. Oculus Quest 2 is a virtual reality (VR) headset that allows users to work, study, and engage in numerous life-imitating and imaginative simulations (H. Valentin et al. 2021 and A. Diar et al. 2022). In the visual output of the device, artificial objects and information can be displayed in the wearer's visual field, which can be interacted with via various gestures as shown in Figure 1b.
The selected VR training software (Mission:ISS) was designed by the L.A.-based Magnopus studio, in collaboration with NASA, the European Space Agency, and the Canadian Space Agency, where these virtual experiments create a true-to-life simulation which lets users visit and explore the International Space Station (ISS) within digital reality and feel what it is like to be in space in a way never before possible (P. James 2022).

(a) (b)

Fig. 1. (a) part of a training sessions at the 3D virtual reality laboratory at NASA's Johnson Space Centre in Houston (A. Diar et al. 2022), (b) Use of cases for Oculus Quest 2 as part of Livestream of the users' view in SETU-Carlow Campus.

Based on NASA's Space Station models, as well as discussions with multiple astronauts and the VR Laboratory at NASA's Johnson Space Centre in Houston, Mission:ISS recreates the International Space Station in painstaking detail. Whilst the idea of becoming an astronaut may be a pipedream for most, with these advanced digital technologies, the trainers can use their virtual hands to do several tasks such as, docking incoming cargo capsules, conducting spacewalks, and performing mission-critical tasks, virtually (A. Diar et al. 2022).
Through the training sessions, this visceral and interstellar experience signifies a new cornerstone of interactive education. The students have the chance to learn the history

of the ISS and hear the inspiring stories of several astronauts in a series of immersive videos. And there is another educational component to the experience, most explicitly in terms of the optional pop-ups to be found. If something is highlighted in yellow when the trainee points at it – a spacesuit, say, or a control console – they can hold the trigger to reveal text and a photo or sometimes a video. Furthermore, a NASA astronaut will talk briefly about their experiences that can help and guide the students in their first-time training sessions.
In addition, a wide range of different representations can be shown, which is not as easily possible with the more traditional basic models. The Mission:ISS software was designed to display different representations, and create different user sessions as well, which gives them opportunities to extend the training sessions and add more flexibility to select a wide range of options (A. Diar et al. 2022 and P. James 2022).
In order to be able to work with this digital environment, the training session started with a short presentation of basic concepts for graphical user interface (GUI), controller options and keys. This section was followed by an introduction to the different representations which the Mission:ISS software can display. The designed sequential procedures can be visualized in Figure 2.
Following the introduction and initial survey, the student had the chance to handle the VR equipment and work through the user interface training session of the Oculus Quest 2 device, helping them to be familiar with gestures requisite to executing a Virtual Reality HMD and two controllers.
Through the demonstration session, the students were shown how to operate the Mission:ISS software. Once the software user interface was explained, the students then worked on the specific tasks individually for approximately 10-15 minutes before completing the second paper-based survey and a short interview.
The directives given to the trainee students within the teaching/training sessions were as follows:
(a) Allow the trainee to wear a helmet while looking at computer displays, whilst simulating actual movements around the various locations on the station hardware where the real astronauts were working.
(b) Visualize and test, a zero-gravity environment using the Touch controllers, as well as examining the effects of zero-gravity on human spatial awareness and balance.

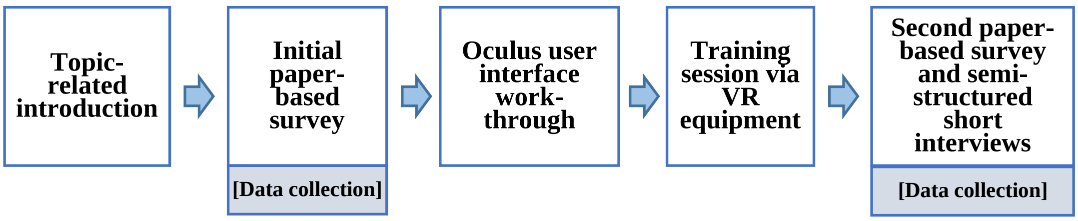

Fig. 2. Structure of the participants' programme.

2.4 Data Collection

The two written paper-based surveys were conducted as the main components of the data measuring and collection stage before analysing the research data using the standard validated tools and techniques. The essential goal of a questionnaire was to monitor and measure the participants' motivation and engagement as well as their experiences before and after using VR tools in the field of engineering education.
The two surveys contained several questions. Generally, there are three recommendations for evaluating user interface: efficiency, multiple perspectives, and tailoring which were proposed by Brooke (1996) (J. Brooke 2018 and J. Lewis 2018).

A System Usability Scale (SUS) questionnaire set for the first and second surveys was created based on these recommendations. A series of questions with multiple choices, some with a 5-point Likert scale (A. Joshi et al. 2015) response and some with text input response was created. A few examples are shown below;

1- Before testing the VR headset; In your Initial opinion, do you think this VR method is better than the traditional method of learning about concepts such as working in gravity/space environments? (Likert scale)
2- After testing the VR headset; How do you rate the user interface of the 3D video? (Likert scale)
3- After testing the VR headset; In your opinion, would this kind of VR learning app improve student learning in engineering? (Likert scale)
4- After testing the VR headset; How do you rate your level of confidence in navigating/using the app? (Likert scale)

Typically, the survey questions evaluated the effectiveness in learning/training especially complex models, features, navigation, User Interface (UI), and overall usefulness of the VR tool in achieving the learning goals.

Most of the participant's educational backgrounds were STEM, 80% of undergraduate students were male and 20% were female. The 5-point Likert scale survey questions were then analysed. After the participants had completed the work phase separately, they were individually interviewed about their experiences, their motivation, and their interests by means of a semi-structured brief interview which detailed results will be published in a separate contribution (the work in preparation).

2.5 Data Collection

The results of the two paper-based surveys were transferred into a spreadsheet software program (Microsoft Excel). Using this tool as a statistical analysis software, the data were analysed on a descriptive basis and factor analyses and correlations were calculated.

The link between the students' opinions before and after the training sessions for VR experiments can provide quantitative data and the ability to measure some factors. Additionally, it allows for the evaluation of the effectiveness of the learning approach adopted, especially in relation to the acquisition of new digital characteristics, the ability to simplify navigation of complex models, and the overall usefulness of the VR tool in helping to achieve the learning outcomes.

3 RESULTS

The results of this research work focused on the users' opinions based on the written surveys. However, some outcomes of the students' reflections will also be presented. The training included a short video explaining what the space surrounding the Earth looked like, as well as an opportunity to look at Earth from the angle of outer space. The participants were unanimous in their opinion that such immersive technologies for displaying educational films were invaluable.

Another question asked to the students focused on their opinions regarding the possibilities of including immersive 3D videos in educational programmes in order to stimulate/encourage people to increase their knowledge of planet earth and new space technologies. Figure 3a shows that 76% agreed and strongly agreed, with 20% are still neutral. Watching movies with virtual, or might even augmented, reality technologies adds new features to exploring one's surroundings, and discovering more precise details. In total 92% of the students classified the 3D-immersive video User Interface as very good, as illustrated in Figure 3b.

Another question asked to the students before and after VR experiments centred on the potential of VR programs and apps to help solve problems/achieve the goals more effectively than traditional teaching and learning strategies. After using the VR immersive tools, student satisfaction increased from 12% to reach 52%, as shown in Figure 4, which leads us to the importance of effective design when it comes to creating learning experiences, which can in turn increase the student's interest and motivations.

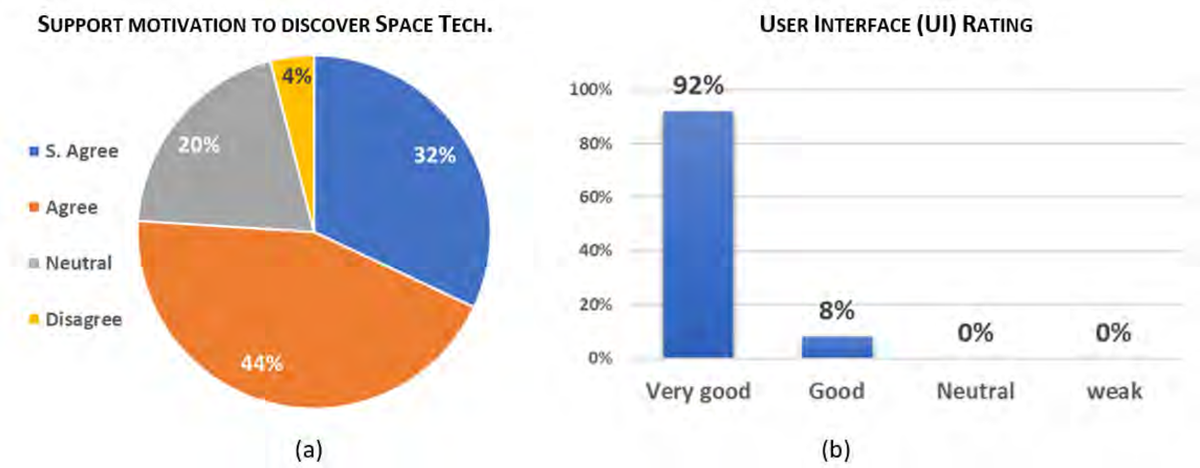

Fig. 3. Summary of the student opinions related to 3D immersive video.

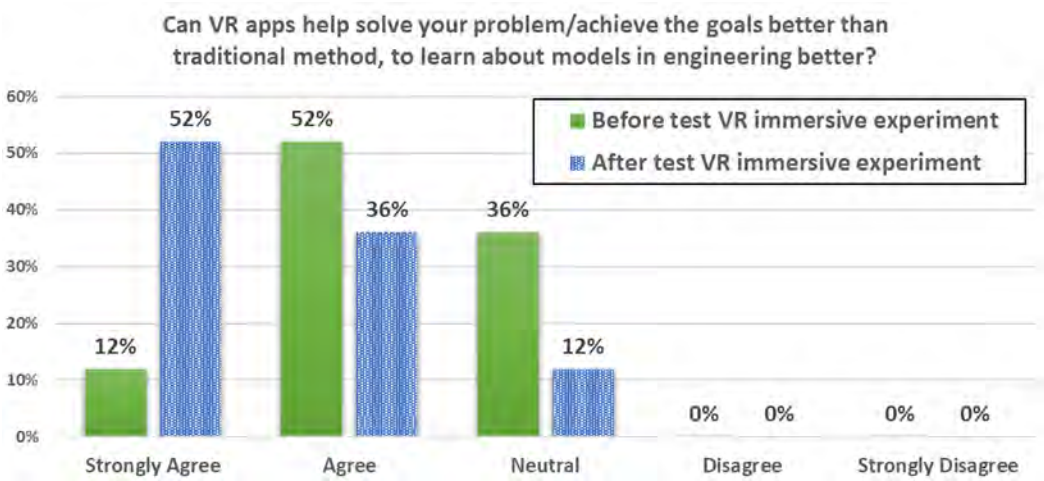

Fig. 4. User feedback before and after using VR headsets in engineering education.

4 DISCUSSION

The VR headset (head-mounted display) and 2 controllers (i.e., Oculus Quest 2 system) were used in this exploratory study as part of the engineering students' class sessions. This VR tool is a relatively new piece of equipment, having being first become available at the end of 2016. It includes a head-mounted display integrated with different high-tech sensors which can work together to support and provide innovative ways of teaching and learning. The exploration of new aspects of student engagement with VR was the focus of the study, which as noted, has been, for the most part, absent in the case of Irish engineering education. To date, there is limited research exploring the feasibility of using such wearable technologies such as bracelets, HMD (head-mounted displays) or gloves in field of higher education programmes.

The initial results related to the impact of virtual reality on learning, showed that the students enjoyed working with VR and they did not face major problems when dealing with it. The students' enthusiasm was observed during the VR sessions, particularly after completing the training part focusing on the Mission:ISS aspect and how to get around and interact with the station. Additionally, they appreciated the opportunity to employ VR devices in undergraduate education and they mentioned that their motivation and interest were augmented, and that their skills were enhanced, thereby illustrating that teaching and learning can be supported using different innovative means and employing digital reality technologies.

5 CONCLUSIONS

These kinds of training techniques and high-tech research using VR can increase knowledge creation and awareness by sparking learners' imagination, and supporting them to experience learning such as testing partial zero-gravity in the international space station, which would not have been otherwise accessible to them within the classroom.

Until the current study, there were a limited number of studies related to embedding virtual reality techniques in teaching engineering in Ireland. In this regard, the outcomes of this research work give new findings that might be related to the higher education sector in general or specifically to engineering fields. Mainly, the results explain that potential students or trainees are supportive of integrating VR technologies and related equipment in higher education programmes, especially as support tools in the laboratory.

ABSTRACT

The bachelor degree in Mathematics Applied to Technology and Enterprise (LMATE) has an innovative structure, working in partnership with industry, involving a transdisciplinarity curriculum plan, with a solid mathematical base including extensive knowledge in statistics, optimization, modeling and programming (Python, R, etc.), along with training in engineering, physics and management.

LMATE presents three differences in relation to other applied mathematics portuguese bachelors degrees: it was constructed upside down towards the usual,

[1] *Corresponding Author:*

S. M. Aleixo

sandra.aleixo@isel.pt

once partner entities (enterprises, public entities and research centers) were consulted on relevant mathematical contents to solve their problems, instead of being created exclusively by the academy; in its curricular plan has optional curricular units from several engineering areas; and is the only bachelor degree in applied mathematics that has an internship integrated.

As LMATE performance evaluation measures the following can be listed: the number of partner entities has increased to 37 currently; demand has been far greater than the offer of vacancies, reaching around 800%; average entry grades have been increasing (from 12.6 to 15.2); and more than 70 of the 176 students who entered in the six years of LMATE have graduated, having done internships in partner entities.

Based on a follow-up study of students who have already finished LMATE to assess the quality of the knowledge acquired and its employability, it is concluded that many of finalists enroll in master's degrees, the majority just after LMATE; others enter the labor market straight away, but all feel that LMATE provided them with adequate preparation.

1 INTRODUCTION

Many of the developments in our society are undoubtedly driven by science and technology, making it imperative to apply different mathematical concepts and methods, most of them driving to optimal results which increase sustainability. In 2021, the UNESCO Director-General said that mathematics support all areas and plays a key role in artificial intelligence and technological disruptions along with algorithms; when global issues such as the COVID-19 pandemic, climate change and sustainability are addressed, the importance of mathematics in responding to current challenges is perceived (UNESCO 2023).

The universe of Mathematics applications is vast, there are several areas of human knowledge, namely all natural sciences and engineering, medicine, economics or social sciences. There are also numerous branches of mathematics to which these areas apply, among which modeling, optimization, statistics or computer science, can be highlighted (Pepin, Biehler and Gueudet 2021, 166). Despite this intrinsically interdisciplinary context, the vast majority of existing classical applied mathematics bachelor degrees have, for students, an apparently limited action in applications.

Interaction with external stakeholders is highly recommended to develop students' skills and abilities. In addition, it is important to adapt students' learning to the needs of stakeholders, allowing optimizing processes and resources, as well as increasing competitiveness, and fostering the sustainability of companies/industry (Hoinle, Roose and Shekhar 2021; Gorgul and Erden 2022, 1206; Herzog et al. 2022). Faced with this reality, one of the authors, as president of Mathematics Department (MD), triggered the construction process of a new Bachelor Degree: LMATE.

2 CONTEXTUALIZATION

LMATE intends, without giving up a rigorous mathematical training, to enable its students to solve issues raised by society, by institutions and companies from several areas or from other sciences and technologies, in close connection with institutions generators of development, competitiveness and more sustainable solutions. In order to base the construction of this bachelor degree proposal, the MD of the Higher Institute of Engineering of Lisbon (ISEL) carried out a careful study about the existing applied mathematics degrees, not only in Portugal but also abroad. This study proved to be particularly enlightening in identifying training combinations not yet explored by national higher education institutions, in which it was still difficult to recognize any connection to institutions and business organizations. Some inspiring degrees were: Industrial Mathematics at Bremen University in Germany, and Mathematics with specialisation in Statistics, Economatics or Mathematical Engineering at Autonomous University of Barcelona in Spain. LMATE was inspired by these degrees with a strong mathematical and computer base, different curricular units (CU) linked to industrial mathematics, modeling and management. However, although these courses have a final degree work with significant weight, they have no connection to companies during the degree like LMATE. Aware of the pertinence and the need to strengthen the relationship between the academy and the community (Feron, Poinsotte and Jossic 2022) the MD established multiple contacts and promoted several work meetings with heads of different companies and entities, many of which have an undeniable economic and social role. These contacts, all of which were well received by enterprises and institutions, resulted not only in a crucial contribution to the structuring of the bachelor degree, integrating fundamental contents into the syllabus of the CU, but also in triggering their participation in seminars and workshops integrated into the degree, as well as the offer of internships, resulted in a unique training offer and an even greater alliance between ISEL and the scientific and technological community. LMATE presents three fundamental differences in relation to other applied mathematics degrees existing in Portugal: 1) It was constructed in the opposite way to the usual, in the sense that the subjects that the partner institutions considered to be relevant to later apply in solving their problems were identified first and after were inserted these themes in the syllabus of the CU. That influenced also which CU that should be part of the curriculum. Instead of the degree being designed solely by the academy; 2) It has in its curricular plan optional CU from the various areas of engineering at ISEL, in order to familiarize students with important areas that they will integrate when they go to do internships at partner entities; 3) It is the only undergraduate degree in applied mathematics that has an internship integrated into its 3-year curriculum structure.

The structure of the proposed degree thus resulted in innovative, forceful and flexible training in the Portuguese reality, both in terms of differentiation in relation to the existing offers in higher education, and in the needs of companies and entities in the country.

3 LMATE

3.1 Bachelor Degree objectives

LMATE intends to develop and apply, in a multidisciplinary context, advanced mathematical and computational methods in the formulation, resolution and interpretation of relevant problems in different domains, in particular real problems raised by the several branches and sectors of activity (many of them improving sustainability). In this sense, LMATE is aimed by candidates with varied profiles and interests, aspiring to provide its students with a considerable set of scientific and professional skills.

The set of CU that make up LMATE, aims to offer its students solid knowledge that will allow them an early and successful entry into the job market, or, if they prefer, the continuation of their studies in masters in a diverse set of areas.

The LMATE curricular flexibility seeks to be made up of current, appealing and multi-disciplinary options, in areas such as mathematics, engineering, physics and management, where the greatest possible advantage is taken of the training offers of other ISEL departments. Throughout the training course, MD has promoted seminars/workshops, carried out by professionals from partner entities, so that LMATE students become familiar with research projects since the first curricular year. The biggest challenges presented by the partner entities are for the internship themes, and the smaller ones will be, whenever possible, object of study in the curricular units designed for this purpose.

The bachelor degree culminates in an internship at a partner entity or in a project that provides:

- obtaining knowledge and experiences advocated by the articulation between theory and practice;
- autonomy in the acquisition of scientific knowledge necessary to carry out the proposed tasks;
- the development of relevant and necessary skills, habits and attitudes for the acquisition of professional skills;
- a closer relationship between ISEL and the community.

By contemplating the elaboration of protocols with partner entities, LMATE favors the integration of graduates in the labor market.

3.2 Students admission

Initially, were assigned 30 vacancies to LMATE for the national competition for access to higher education (CNAES). In 2018, due to national politicies it became 28 vacancies.

Since its first year of operation, LMATE has had all of its vacancies filled in the first phase of the CNAES. The few registrations not carried out in this phase, automatically transferred to the second phase, were also completely filled out. Between 30% and 40% of the placed candidates choose LMATE as their first option.

Some statistics about students who entered LMATE can be consulted in Table 1:

Table 1. Statistics of candidates who joined LMATE through CNAES

Year	Min.Ph.1	Max.Ph.1	Aver.Ph.1	Plac.Ph.1	Min.Ph.2	Max.Ph.2	Aver.Ph.2	Plac.Ph.2
16/17	11.84	14.00	12.66	30	13.44	13.96	13.70	7
17/18	13.20	15.66	13.80	30	14.68	16.26	14.96	3
18/19	12.80	15.98	13.76	30	13.98	15.50	14.57	6
19/20	13.34	15.66	14.17	28	14.34	15.04	14.69	6
20/21	13.36	16.06	14.24	28	14.74	15.96	15.25	2
21/22	12.72	15.54	13.86	28	14.42	15.42	14.70	6
22/23	14.22	17.20	15.21	29	15.46	16.54	16.04	4

LMATE has recurrently had a demand far greater than the offer of vacancies in any of CNAES phases. Regarding the *1^s* phase, Table 2 has some relevant data.

Table 2. Number of 1st phase LMATE candidates, vacancies and demand rate

Lective year	Number of candidates	Number of vacancies	Demand rate
2016/2017	70	30	233%
2017/2018	173	30	577%
2018/2019	240	30	800%
2019/2020	165	28	660%
2020/2021	161	28	772%
2021/2022	109	28	389%
2022/2023	211	29	728%

3.3 Curricular Structure

The curriculum plan proposed for LMATE was distinguished in several aspects of the structures offered in different institutions with training programs in the same area of knowledge in Portugal. The offer of CU in the first year of the study cycle is varied (see Fig.1), covering some fundamental topics for the student to acquire the intended base skills. The diversification of competences is achieved by the progressive offering of a wide range of options, in which the direct contact with the several scientific areas of ISEL is privileged and which will translate into easier adaptation to the interdisciplinarity required by real problems. This way, the student has the possibility of organizing his study plan with predominance in application in one of the engineering areas of his interest. The internship/project (see Fig.2), which may extend to partial regime throughout the 3rd year curriculum (modality 1) or focus on the 2nd semester of the 3rd year (modality 2), will materialize the connection to concrete problems of the business world, consistent with the nature of the study plan. The main areas of LMATE study are: mathematics, statistics, operational research, optimization, numerical analysis, modeling, simulation and programming. LMATE curriculum plan includes 19 mandatory and 7 optional CU. Between the mandatories CU: 4 are in pure mathematics; 1 in numerical analysis that allow them to learn alternative methodologies to solve insoluble mathematical problems analytically, and other 2 more advanced, mixing analytics and numerical analysys; 1 of Physics, useful in formulate, modelate and solve some kind of specific problems; 4 are in statistics, which enables students to acquire strong training in this necessary area, much requested later in internships and in professional life; 2 in operational investigation and optimization, much useful in solving real labor market problems, allowing to assist decision-making; 1 in Management that allows students to evaluate the economic impact of the new methodologies they apply, and finally, 1 of Modeling where real problems are solved as preparation for the internship. In addition to math options (like Quality and Reliability Control, Bayesian Statistics or Operational Research Complements), students have annually a vast list of other optative CU in physics, engineering and soft skills; namely Machine Learning, Artifitial Intelligence, Data Bases, General Chemistry, Electricity Networks and Telecommunications, and Marketing and Interpersonal Communication.The dynamic structure of the LMATE curriculum plane should be emphasized, in the sense that the CU programs changes, given the pedagogical experience that has been gaining with the teaching development, aided by the contribution of partner entities regarding the performance of students in the internships. The contribution of LMATE partners was very important in creating the bachelor degree, but it remains crucial for its update, so that it will increasingly meet the needs of the labor market that becomes extremely demanding.

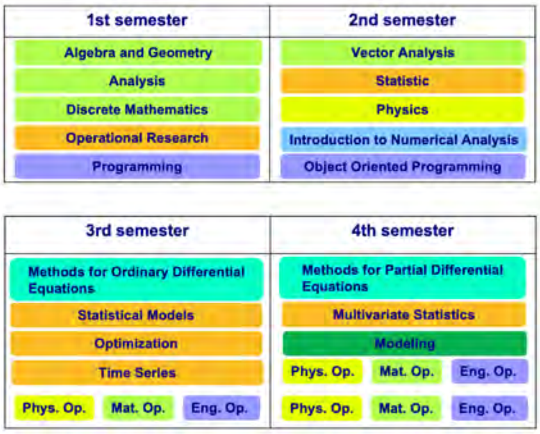

Fig. 1. LMATE Curriculum – 1st and 2ndyears

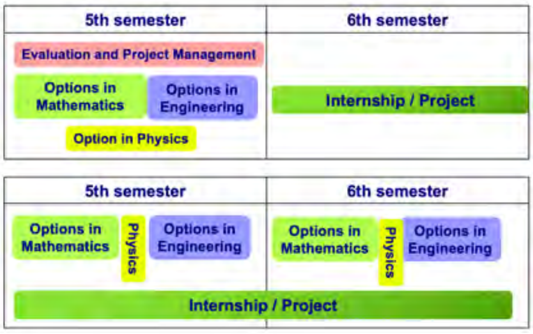

Fig. 2. LMATE Curriculum – 3rd year

3.4 Teaching and Evaluation Methodologies

In general, the several CU work on a theoretical-practical basis, with some working in a computer lab. All subjects have support lessons beyond class hours, and in addition, the teachers are always available to answer questions, existing a great proximity between students and professors. The CU assessment comprises a theoretical part by tests or by exam, but always has a practical component consisting of one or more individual or group assignments. In most cases, practical assignments are submitted to an oral presentation and discussion, which allows validating the learning outcomes and providing public speaking skills for students future professional life. The strong acceptance of the works carried out by the students in the internship by the partner entities of LMATE, is a strong indicator of the adequacy of the learning results obtained and consolidated throughout the degree.

3.5 Coordinating Committee

Since the beginning of operations, LMATE has had its coordinating committee (CCLMATE) divided into two parts: one academic (as usual) and the other linked to partner entities, responsible by: 1) attracting new entities; 2) determining enterprises mathematical problems for internships and for exercises in classes; 3) booking partner entities workshops/seminars; 4) organizing events involving partners; 5) listening to the opinion of these entities regarding: a) the performance of students in internships, b) students knowledge and c) possible suggestions for the insertion of new syllabus contents in the CU of the degree. This way of operating LMATE has proved to be extremely versatile and profitable.

3.6 Partner Entities

The main added value of LMATE is undoubtedly its partnership with enterprises and institutions, allowing an enriching exchange between academia and the job market, beneficial for both parties. At the creation of LMATE, there were already a dozen partners in several sectors. This number has been growing, so that currently LMATE has thirty-seven protocols signed with partner entities, which essentially cover three types of collaboration: 1) participation in seminars; 2) offer of curricular internships to LMATE students and 3) consultancy projects carried out by ISEL MD professors. These partners cover a wide range of areas, namely, **energy**: EDP, GALP, REN; logistics/transport: Transportes Paulo Duarte, Wurth, A-To-Be (Brisa Inovação), Delta; **metalworking/equipment industry**: Sandometal, Exide; research: CDRSP(IPLeiria), LNEC, IPMA; **pharmaceutical/health industry**: Hovione, Grupo Lusíadas, Alliance Healthcare; **services**: Águas do Tejo Atlântico, Câmara Municipal de Lisboa, Infraestruturas de Portugal, CTT, Tecmic, Secretaria Geral da Economia e Mar, Wikiservice, Carclasse, Antúrio, ISX4 Analytics, Jerónimo Martins; **insurance**: Allianz; **consulting/investment**: Closer, Milestone; Bring Global, Dolat Capital; **telecommunications**: Celfinet, Solvit; mold industry: Iberomoldes, Centimfe; **lighting**: Arquiled; media: Media Capital.

3.7 Internships and Projects

The number of LMATE internships and projects has been growing: 5 in 2018/19, 14 internships and an anual project in 2019/20, 18 internships and 3 projects in 2020/21, 27 internships and 2 projects in 2021/22. In 2022/23, as a result of the pandemic, the number of internships had decrease to 14 and 1 project, accompanying the decrease of students in higher education. As examples, some titles of internship reports are listed, namely: Wind Power Forecast with Machine Learning (REN), Optimization of the allocation of transport services (Tecmic), Use of machine learning techniques in predicting the capacity of LTE cells (Celfinet), Estimate Fishing Effort and Predict Operating Gear (IPMA) and Empirical Statistical

Modeling of Equipment with Monitoring of Lubricants in Service for Proactive Maintenance (Galp).

3.8 Path of students who completed the LMATE degree

Currently, there are about 80 students enrolled, 62% male and 38% female. So far LMATE has 67 graduates. A follow-up study was carried out on the path of students who had already completed the degree, contacting them by phone or by email. Many of the LMATE finalists go on to master's degrees, most of them right after finishing the LMATE. Others enter the labor market straight away. According to the study, it has ben concluded that: 1) students who are attending or have already completed a master's degree considered themselves well prepared by LMATE for these masters. Many of the topics to be addressed in these masters have already been covered in LMATE; 2) students consider that the computational tools used in LMATE are an enormous asset in the master's degrees, in addition to helping them to carry out their functions in internships at LMATE's partner entities, as well as in their performance in enterprises where they are currently working; 3) students who are already working consider that the internship was very important for them to enter the job market. Also according to the same study, around 30 former LMATE students are already working in several areas of applied mathematics and computing, namely in consulting, banking, insurance and software companies.

4 FINAL CONSIDERATIONS

LMATE has been successful since its creation in 2016, once it has always filled its vacancies and has a dropout rate around 10%, as others ISEL bachelor degrees. Its students recognize the differences that distinguish this applied mathematics degree from others on the market, due to: 1) its solid teaching in mathematics, but at the same time practical; 2) the use of several software; 3) its dynamic construction aided by partner entities; 4) the support and availability of teachers; 5) internships integrated into the curriculum at well-known enterprises and institutions, which bring them closer together and facilitate their entry into the job market. LMATE finalists have enrolled in master's degrees at ISEL and at other important higher education institutions, and the knowledge acquired at LMATE has proven to be quite adequate for carrying out these masters degrees. Half of the students who finished LMATE (some are still doing their master's) are already in the job market applying their mathematical knowledge. The others are mostly carrying out the master's degree exclusively.The creation of LMATE was an innovation, attracting students who otherwise would not come to an engineering school, allowing a fruitful exchange of knowledge and experiences between these students and engineering students who share some UC and live together at the school. LMATE has conquered its own space in the higher education of Applied Mathematics in Portugal, greatly contributing to this, the performance of its students in internships at partner entities who recognized their work. Since LMATE students, as workers, contribute to the optimal solutions of many processes/resources, they are improving the sustainability of our world.

FUNDING

This work is partially financed by national funds through FCT – Fundação para a Ciência e a Tecnologia under the project UIDB/00006/2020.

***Conference Key Areas**: 2. Embedding Sustainability and Ethics in the Curriculum, 15. Curriculum Development*
***Keywords**: Ethics, Integration, Reflection, engineering programme transformation, curriculum transformation*

ABSTRACT

Many technical universities alike, TU Berlin is in a future-oriented process of programme transformation to invite a holistic perspective on technology which includes critical thinking and ethical reflection. To this end, TU Berlin recently issued a general study guideline calling for an orientation of all programmes toward sustainable development. Accordingly, students should know about the historical, social and cultural contexts of science and technology and learn to reflect on the ethical consequences of their actions. Together with training in good scientific practice, this content should comprise 12 ECTS in each respective BA and MA programme. With only minor integration of this content in the current curricula to date, this transformation presents a significant challenge since courses need to be realigned as well as replaced. To find an answer, TU Berlin’s engineering faculty initiated a think tank in spring 2022, bringing together students, teachers and administration to search for ways of integrating ethics as well as science reflection and technology reflection to foster sustainable development. In our contribution we present a first outcome, namely the integration framework ENG+ for programme design which allows for the incorporation of ethics and strengthening of core values such as diversity, sustainability, and good scientific practice. In the ENG+ framework, we introduce the strategies of advancing and complementing as well as six corresponding measures for integration – emphasising, empowering, embedding, enabling, enriching, and encountering. We explain how they jointly contribute to the overarching ENG+ concept which brings together ethical reflection and sustainable development.

1 INTRODUCTION

TU Berlin's new General Study and Examination regulation requires that at least 12 credit points (in the following addressed as ECTS) need to be devoted to ethics, science reflection and technology reflection in every degree programme to foster sustainable development. Hence, the key question is: how can these topics be implemented in the TU Berlin engineering programmes? As the structure of the programme design is fixed due to the required 180 ECTS for Bachelor's and 120 ECTS for Master's degrees, a redesign is needed. The TU Berlin has approximately 35,000 students, of whom 5,454 are enrolled at the *Faculty of Mechanical Engineering and Transport Systems*. This requires an enormous transformation at our institution, which will take a lot of time and resources. Furthermore, it requires a fundamental change in the approach to teaching philosophy as well as to engineering. Since the TU Berlin has thus far lacked experience in systematically implementing ethics, sustainability, and gender and diversity perspectives in study programmes, the faculty initiated the *Think Tank Technology Reflection* in spring 2022 where students, teachers and administration come together in monthly meetings. As members of the think tank, we want to present the ENG+ framework for programme transformation as a first result from the think tank process.

Regarding the overarching aim of the transformation, we want to point out three aspects which specify the unique starting point of our engineering faculty, in terms of its opportunities and challenges. Firstly, as engineers, we are already sustainable in terms of cost and material reduction. Hence, there is a basic understanding of sustainability and approaches at hand which can be built upon. Secondly, due to the engineering departments of our institution (e.g. transport, product development, machine design, human factors) we have a good thematic foundation for human-centred design processes which can be extended to include broader societal and ethical reflections. Thirdly, there is a strong emphasis on making and doing, which comes with a lack of discussion culture in engineering education. The latter, however, is essential for implementing ethics, science and technology reflection. Thus the appreciation and training of discussion and reflection represents a major challenge when it comes to curriculum transformation.

Our paper starts with an overview of the main challenges reported in the literature (Sec. 2). How these will be tackled by the strategies and measures of the ENG+ framework is the topic of Section 3. Section 4 shares the challenges of the ongoing process. We conclude with an outlook of the next milestones.

2 CHALLENGES OF INTEGRATING ETHICS, SCIENCE AND TECHNOLOGY REFLECTION INTO ENGINEERING PROGRAMMES

Since the 1980s the necessity of ethics education and the importance of strengthening reflection competencies has been consistently highlighted in the literature of engineering education (Grunwald 1999; Mitcham and Englehardt 2019; Sætra and Danaher 2022; Fiesler, Garrett, and Beard 2020). Nevertheless, advancement has been slow, and "the question of the integration of the ideal of engineering education for ethics has been largely ignored" by academic research (Martin, Conlon, and Bowe 2021, 24). Although there are good examples of the integration of ethical reflection into engineering programs, such as programmes at TU Twente and TU Delft (van de Poel and Smuga-Fries 2015; Doorn 2021), there are still challenges to overcome.

In the literature of engineering ethics education, two main challenges have been reported. Firstly, teachers often struggle to understand and ensure alignment among the variety of theoretical frameworks, learning objectives, instructional activities, and assessment methods. There are numerous interrelated learning objectives, but no consensus in the literature as to which strategies are most effective in achieving them or which objectives should be prioritized (Martin, Conlon, and Bowe 2021). This means that teachers find it particularly difficult to formulate ethical learning objectives for their courses or modules (ibid.) – especially because of a lack of familiarity with ethical issues and methods. This raises the problem of deriving appropriate didactic as well as pedagogical content and methods to connect ethical issues to technical ones. To address this issue, co-teaching activities can be implemented, in which engineers work together with philosophers and social scientists to integrate socially relevant aspects into technical contexts and to show that ethics and technical thinking go hand in hand. The approach can be improved by integrating ethical mini-modules into existing modules, so that students become habituated to reflecting ethically. In this way, students can learn about a variety of concrete ethical issues and problems in their field.[1] Co-teaching also provides another additional advantage, as "interdisciplinary ethics learning provides a better basis than disciplinary ethics learning" (Mitcham and Englehardt 2019, 1756).

Secondly, institutional framework conditions and a lack of support from the administration represent another major obstacle. The challenges listed above are further compounded by institutional constraints: the prominence given to ethics in the curriculum is critical to conveying the message to students that ethics is not a peripheral issue in engineering, but an essential aspect of their profession (Mitcham and Englehardt 2019; Fiesler, Garrett, and Beard 2020; Martin, Conlon, and Bowe 2021). This is why the "top-down support to secure appropriate embedding in the university" cannot be stressed enough (Mitcham and Englehardt 2019, 1756). To ensure appropriate embedding in the university, support is needed from the administration. As it is clearly an important, and certainly open, question how to make room for new content in full curricula, thus a coherent and focused overall strategy for a unified curriculum is needed. In order to make societally relevant aspects central to education, having a coordinated institutional response is a central requirement (cf. Martin, Conlon, and Bowe 2021). Support from the institution is also needed to implement support services such as professional training, joint

[1] A good example of an integrative, overarching approach can be seen at the TU Twente and TU Delft ("RESTS REflection on Science Technology and Society (RESTS)" n.d.; van de Poel and Smuga-Fries 2015; Doorn 2021).

development of course content or teaching (for example, in the sense of co-teaching), or mentoring and networking opportunities (cf. Mitcham and Englehardt 2019). Prioritization of an implementation strategy is the only way to ensure systematic implementation of a unified curriculum.

A key learning from these reports is that a coherent and targeted strategy at the institutional level is needed to implement ethics systematically in engineering programmes. As a first step, this requires an overarching concept at the programme level which breaks down to the second step of a curriculum redesign at the course level with appropriate learning goals. To set such goals, working together with philosophers and social scientists as well as program committees is essential for connecting ethical reflection to the discipline-specific content of the programs. Additionally, further support from the institution is necessary regarding training courses to help teachers learn about ethically relevant issues in their discipline, support them in formulating ethical learning goals, and develop teaching material for their courses.

3 ENG+ FRAMEWORK: INTEGRATING ETHICS, SCIENCE REFLECTION AND TECHNOLOGY REFLECTION INTO ENGINEERING PROGRAMMES

3.1 Background

A starting point for the transformation process at TU Berlin was a long-range, university-wide vision for teaching which was adopted in 2018. It includes educational goals and combines academic education with personal development:

> *The mission statement for teaching […] forms the basis for all regulations, rules and strategies that determine teaching at the TU Berlin. It must be reflected in all study and examination regulations, in the curricula and in quality management for studies and teaching. […] Our teaching enables students to face technological change and its social impact with creative ability, a sense of responsibility and high professional qualifications. (Technische Universität Berlin 2018, 5-6)*

This mission statement has been transformed into a binding requirement for all Bachelor's and Master's programmes by the new General Study and Examination regulation (AllgStuPO):

> *[1]In the study programmes, the rules of good scientific practice are taught at the earliest possible stage and continuously trained. [2]Students learn to place knowledge and action in an overarching historical, social and cultural context and to consider ethical consequences of action in order to be able to contribute to sustainable development. [3]It is to be ensured that all students have completed relevant study content amounting to at least 12 ECTS by the time they graduate. (Technische Universität Berlin 2021, §44, 3)*

To respond to the new AllgStuPO, members of the *Faculty of Transport and Mechanical Engineering* launched the think tank at an internal faculty meeting in spring 2022. Its aim is to develop an overarching strategy for integrating ethics, science reflection and technology reflection. It should serve as a vision for curriculum redesign and, as a follow-up step, the (re)design of courses. The think tank's monthly hybrid meetings brought together students, teaching and administrative staff, as well as two women's representatives. Since the think tank raised interest also from other faculties as well as the university's central administration, we were able to draw on perspectives across the university.

3.2 ENG+ Framework: Strategies and Measures

As a first result of the think tank, we want to present an overarching heuristic for integrating ethics as well as science reflection and technology reflection to foster sustainable development. Methodologically, the think tank started with a literature review of the key learnings and challenges when trying to integrate ethics into engineering education (see section 2). A coherent and targeted strategy at the institutional level was then identified as the central goal. Subsequently, a conceptual analysis of possible ways to connect ethical reflection to the discipline-specific content of the programs was conducted. As a result, the integration framework ENG+ offers different ways of implementing these topics in programme design. Contextualizing engineering problems allows students to see their broader societal and environmental impact, to understand the interrelation between technology and society, and to grasp potential ethical risks in emerging technologies. From a traditional (disciplinary) point of view, this endeavor is of a deeply interdisciplinary nature, as it brings to the engineering curriculum knowledge and competencies rooted in philosophy, humanities, and social sciences. However, ENG+ is less about including additional disciplinary viewpoints, but rather introducing students to holistic thinking and enabling them to experience the intrinsic complexity of technology.

To arrive at an integrated programme design, ENG+ draws on two major strategies, advancing and complementing, which need to go hand in hand (see fig. 1).

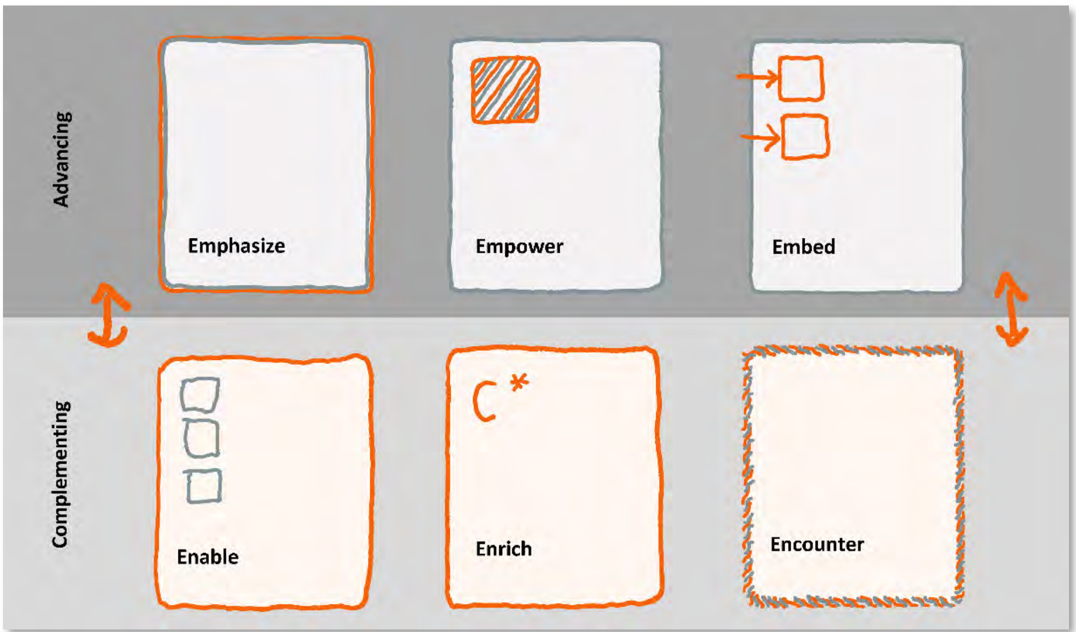

Fig. 1. ENG+ framework to integrate ethics, science reflection and technology reflection into engineering programmes. Graphics: S. Ammon 2023

Advancing aims at the further development of existing STEM courses to show the relevance of ethics and reflection for engineers, as well as the connection to STEM topics. Advice, training and targeted support for STEM teachers will play a key role here. Advancing comprises the following measures:

- **Emphasize**: further development of existing STEM courses that have already integrated ethics, science reflection and/ or technology reflection and establish the contribution of these areas to sustainable development within the framework of the subject of the course. Targeted emphasis will make this orientation more visible and strengthen it.
- **Empower**: further development of existing STEM courses that have not yet integrated ethics, science and/ or technology reflection. Through targeted guidance and training, teachers are empowered to integrate ethics, science and/or technology reflection and to establish the contribution of these areas to sustainable development within the context of the course topic.
- **Embed**: further development of existing STEM courses that draw on the expertise of ethics, humanities and/ or social science experts to embed ethics, science reflection and/or technology reflection. For this purpose, mini-modules (e.g., 2-6 h per week) are integrated into the existing course in order to incorporate questions of ethics, science reflection and/or technology reflection directly into the overarching topic of the course.

Complementing furthers the development of new courses in the area of ethics, science reflection and technology reflection. They should comprise topics such as research ethics, professional ethics, technology ethics, environmental ethics, technology assessment, history of science and technology, or science and technology studies. It will be essential to tailor the content of these courses to topics of the respective STEM disciplines. We recommend that interdisciplinary co-teaching be given a high priority. Complementing comprises the following measures:

- **Enable**: A foundational course that introduces basic ethical concepts and trains ethical reflection practice. The added value of ethical knowledge and ethical competencies for sustainable development is to be made tangible by directly linking ethical issues to topics in the STEM fields. The contextualization of technology and science and their critical reflection play an important role.
- **Enrich**: In-depth courses in the field of (applied) ethics, science reflection and technology reflection. Students can earn certificates, which certify a focus of study. The Faculty of Mechanical Engineering and Transport Systems offers in-house certificates such as the Berlin Ethics Certificate (see Ammon et al. 2022) and the Sustainability Certificate.
- **Encounter**: Interdisciplinarity can be experienced through collaborative teaching and learning in diverse settings by teachers from STEM areas and humanities or social sciences. Differing disciplinary cultures and perspectives can be experienced, along with the relevance of interdisciplinary cooperation. The collaborating teacher acts as a role model.

For a successful programme transformation, the strategies of advancing and complementing need to resonate with each other. That means a complementary curriculum design, mutual references of the courses, as well as an overall vision which draws on sustainable development need to come together. This also implies a *cultural change* which strengthens a culture of togetherness and encourages cooperative forms of teaching and learning. An appreciation of diversity, a non-discriminatory environment, the ability to change perspectives and a constructive approach to divergent opinions as well as to inter- and transdisciplinary are all important elements of this strategy. Teachers serve as key role models in this cultural change.

ENG+ as an overarching vision for programme design ensures that the different measures interrelate with each other. It also shows that it is not required that all courses address the topics of ethics, technology reflection and science reflection to the same extent. The integration of ethics, science reflection and technology reflection is more than the sum of different measures; thus it is the overall effect that counts.

4 HURDLES IN IMPLEMENTING THE ENG+ FRAMEWORK

Since the new General Study and Examination regulation leaves open how the 12 ECTS are covered in the degree programmes, it is up to the programme directors to decide. For the implementation of the ENG+ framework, we suggest a pragmatic approach in which 6 ECTS are anchored in the engineering programme by advancing and another 6 ECTS by complementing measures.

For **complementing**, a best practice example can be found in the physical engineering programme which has introduced an elective area for students to choose among courses on ethics, sustainability, as well as gender and diversity. However, choosing e.g. a course on sustainability would not necessarily imply that students are taught ethics. This leaves open the question of how it can be ensured that every student learns about basic concepts and approaches of applied ethics.

Another obstacle is that traditional, conservative ways of thinking that can cause difficulties in creating space for new topics in the curriculum. Teachers who see the training of technical competences as the sole goal of engineering education may be resistant and underestimate the relevance of critical reflection and the ability to act sustainably and responsibly.

When it comes to **advancing**, a high level of topics surrounding ethics, science reflection and technology reflection is desirable. However, not every course will be suitable to cover these issues in a meaningful way. For courses like linear algebra or other basic mathematical subjects, an integration might seem rather forced and far-fetched. The advancing strategy also comes with measuring challenges for examination administration. Once the topics are dealt with in an integrative way, how can the 6 ECTS be detected? For example, in a 6 ECTS course which deals to some extent with issues of gender and diversity, how many transformation points does it cover? Should a course which deals with the design of wind turbines be counted in full towards covering sustainability, simply because wind turbines are counted as renewable energy? There are currently no sensible answer to such questions.

In addition, the strategy of advancing requires that teachers be empowered to integrate ethical issues into their technical courses. This requires expert advice and support or training for teachers. Probably the biggest obstacle to the implementation of this strategy is funding, as well as the creation of free time in everyday university teaching. The use of initiatives to promote innovation in teaching, as well as centralized university training, can provide at least some support. Also, teachers must be encouraged to further develop themselves and their courses in this direction. This requires suitable incentive systems.

At the same time, however, this can also contribute to the cultural change needed to support the overall transformation process. Raising awareness among faculty members through structural measures and promoting formats for exchange and networking between teachers can contribute to a culture of togetherness. Collaborative forms of teaching, which could contribute to this cultural change, currently face administrative obstacles. For example, the crediting of co-teaching courses cannot be taken into account in teaching performance according to effort. Existing calculation models should be reviewed to ensure that teachers have the freedom they need to develop themselves and their courses. It is clear that the transformation process needs to be supported by overarching measures, which still need to be identified.

5 OUTLOOK

After having developed the ENG+ framework, the next step will be its implementation and testing within a prototypical engineering programme. To this end, a process of quality assurance needs to be developed, which includes reporting to and feedback from the executive board. The process of redesigning programmes as described above takes time, a lot of resources and commitment. Thus it is important to raise awareness and empower teachers to integrate ethical issues into their courses. It is also necessary to have administrative and professional support for the change process. To this end, we want to use the ongoing think tank to encourage exchange and networking among faculty members, as well as to facilitate formats such as workshops, peer-to-peer consultations, mutual shadowing, expert support and learning from other institutions.

6 ACKNOWLEDGMENTS

We thank the members of the *Think Tank Technology Reflection* for the many stimulating discussions that form the basis of the reflections in this paper.

ABSTRACT

This paper presents a collaborative learning course in which students from four universities in different Asian countries work in mixed teams to learn how to develop user-centered products and solve problems in a hands-on way using the Design Thinking framework. For the past three years, the courses were conducted entirely online. Cooperation and collaboration among diverse people from different backgrounds are essential to solving the social problems facing the world today. Like many universities, we have been actively sending our students abroad to provide opportunities to experience diverse cultures and values, but the pandemic has made it very difficult to travel abroad for the past three years, forcing universities to shift from face-to-face classes to online classes. The pandemic has made it extremely difficult to travel abroad for the past three years, and universities have been forced to shift from face-to-face to online classes. During this time, four Asian universities, to which the authors belong, have jointly launched an online problem-solving collaborative learning course aimed at supporting students to "No one will be left behind," as stated in the SDGs.The structure of the course, profiles of participating students, improvements to the course, student evaluations, and challenges found are described.

---

1 INTRODUCTION

1.1 Context and Motivation

The year 2020 forced education into chaos caused by the Pandemic. University students in Asia were no exception. Learning and teaching platforms shifted to online, and faculty and students who viewed the face-to-face teaching/learning format as self-evident were in dire straits. Leaving universities as a temporary evacuation made many international students challenging to come back due to travel constraints. Faculty staff worked hard to find sustainable ways to include all the students worldwide to keep them connected to the learning process.

Collaboration skills, English language skills, and cross-cultural understanding are necessary for engineering students to work together in the future to solve social problems that transcend national borders. Japan’s Ministry of Economy, Trade and Industry expressed the expectation to foster students with good social skills and expertise. It introduced the requirement for competitive workers in ‘Fundamental competencies for working persons in the era of 100 years of life and recurrent education.’ in 2018. (METI 2018) ASEAN countries are no exception in developing human resources with 21st-century skills. (UNICEF 2019) Thus, the authors were on the same page in building a program to meet our shared goals to help students improve problem-solving skills, and communication skills, especially in English language collaboration skills, and cross-cultural understanding.

A pilot project started online in 2020, “Global Collaborative Learning: Design Thinking PBL(GCL-DT-PBL)” for engineering students between a Japanese and a Malaysian university, was a countermeasure for sustainable education against the Pandemic devastated teaching and learning environment. Then in 2021, two other ASEAN universities joined the loop, and *GCL-DT-PBL* became a full-fledged 4-year project, inviting many more students from diverse cultures. The following sections will describe the structure and implementation of the program, the analysis of student engagement relevant to the program goals, and the findings.

1.2 Program Structure and Implementation

Many researchers have found the effectiveness of PBL as a means of learning as it is student-centered and enhances real-world problem-solving skills, higher-order thinking, and self-directed learning compared to the classic learning approaches. (Du et al. 2009)

Design Thinking is widely applied in many fields, including architecture and urban planning (Rowe 1986), product design, businesses, and education. (Brown 2008) (Kelley and Kelley 2013) Multicultural PBL was integrated into the Design Thinking framework as the program's instructional design based on our common goals. (*Table 1.*)

Table 1. Global Online Collaborative Learning: Design Thinking PBL (GCL-DT-PBL)

Year	Participants	Universities	Duration	Platform	Theme
2020	20	2	7 days (14hrs)	Online	Innovation in COVID-19 Crisis
2021	36	4	6 days (30hrs)	Online	Innovate UTM Campus Cafeteria
2022	31	4	6 days (30hrs)	Online	Innovate UTM Campus Cafeteria

Fig. 1. Design Thinking Process
(The first author created using Canva)

Fig. 1 Shows five steps design thinking model applied and is based on a guideline Stanford Design Thinking of GCL-DT-PBL. Test in Stage 5 was not conducted in 2020 and 2021 due to the constraint caused by the Pandemic but held face-to-face in 2022 in Malaysia with participants from three ASEAN universities. Japanese university was unable to make it because of travel constraints.

2 METHODOLOGY

Data Collection and analytical method

The Google Forms questionnaire was sent to the participants after each program. Responses were collected, and the content was analyzed using text mining software KHcoder. (Higuchi 2016)(Higuchi 2017) Content analysis is an analysis of the content of the communication. Analyzing the written content, especially in the responses to the questions collected after the program is over, helps understand the engagement of the participating students. Text mining is an analytical method to capture potentially useful information from document data. *Table 2.* shows the elemental attribute composition of the data used in the analysis.

Table 2. Elemental attribute composition of the data used

Year	Response	Participants	Number of universities
2020	16	16	2
2021	36	36	4
2022	9	31	4

The focus of the analysis was to explore the students' engagement. The response items text analyzed include expectations for the program, how the programs met the initial expectations, the best part, and the challenges the participants met.

One helpful method for examining text mining results is to read co-occurrence networks applied in our study. A co-occurrence network is a graphical representation of the distance between extracted words. Larger circles connect words with high frequency, and darker lines connect words close to each other. The co-occurrence network allows us to see how frequently occurring words are combined. The context in which the term was used can be deciphered by returning to the description's original text.

3 RESULTS AND FINDINGS

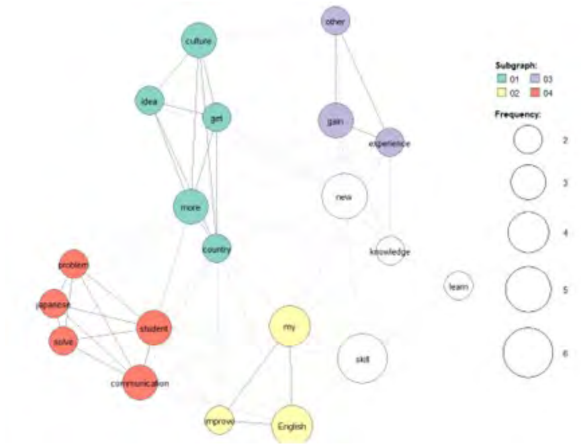

Fig.2 2020 Initial Expectation

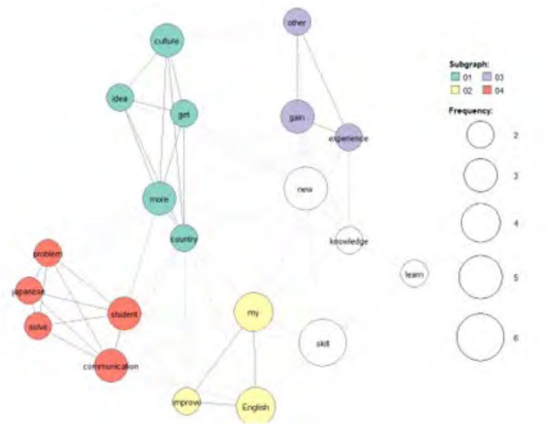

Fig.3 2020 Consistency with Expectation

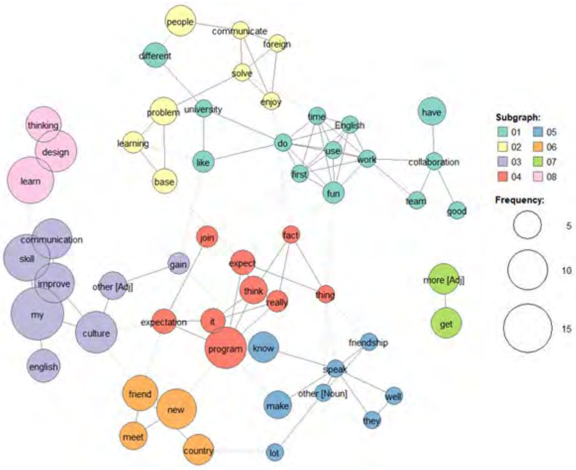

Fig.4 2021 Initial Expectation

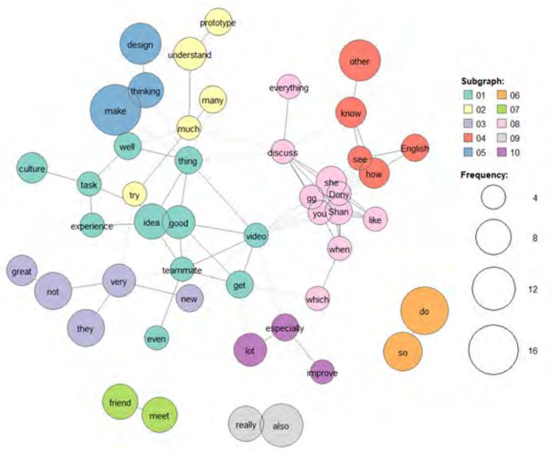

Fig.5 2021 Consistency with Expectation

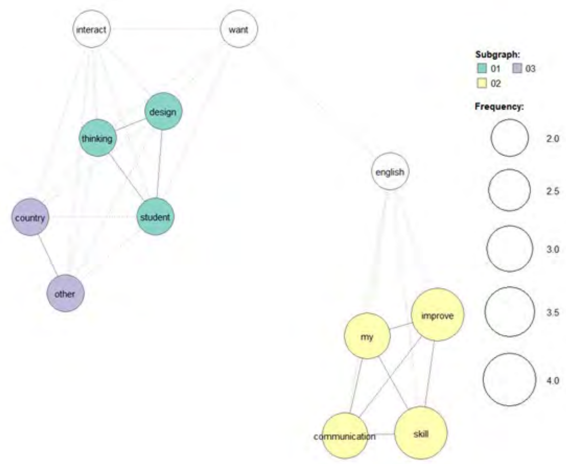

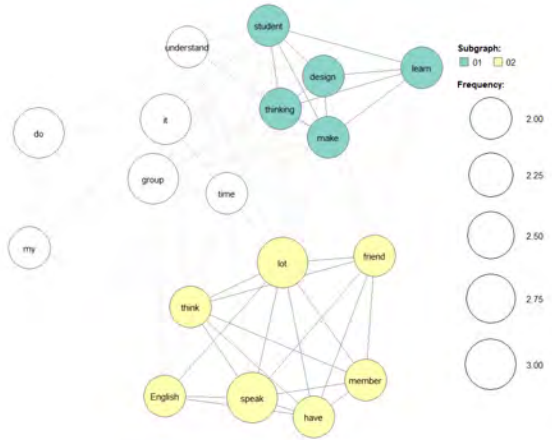

Fig.6 2022　Initial Expectation　　*Fig.7　2022 Consistency with Expectation*

The notably common initial expectations for the three programs in 2020-2022 were: 1) To learn about other cultures and work with new friends and 2) To improve communication skills in English. Few expressed the expectation for learning Design Thinking driven problem-solving. However, the responses to the question about whether the program met expectations were different. Among the familiar words that strongly link the three programs is <u>design</u>-<u>thinking</u>-<u>new</u>-<u>experience</u>-<u>make</u>. This suggests that problem-solving and prototyping in a design thinking framework was a fresh and meaningful experience for the participants. Below are the textual statements extracted from the KWIC concordance showing how the aforementioned linked word groups appear.

- *I 've done <u>new</u> and challenging things from this program .*
- *I still gain a lot of knowledge such as about <u>design</u> <u>thinking</u> , <u>new</u> skills on how to <u>make</u> a prototype mobile apps -LRB- which actually was asked by a company that is currently interviewing me for my internship -RRB- and also <u>new</u> <u>experience</u> .*
- *we must <u>make</u> a project and that 's it really great <u>experience</u>*
- *I have found a <u>new</u> achievement for myself during this program*

KWIC concordance is an abbreviation for keywords in context. It is possible to see which words that appear at the top of the list of extracted terms are used in the sentence. KWIC concordance lets us see how frequently words are used in a sentence.

Regarding the degree of conformity with the original expectations, all but one of the respondents in all three years indicated that the program met their initial expectations. The reason statements of the participant whose expectation was not matched show that the greatest expectation for the program was to improve their English proficiency, as one stated, "My proficiency level still remains the same."

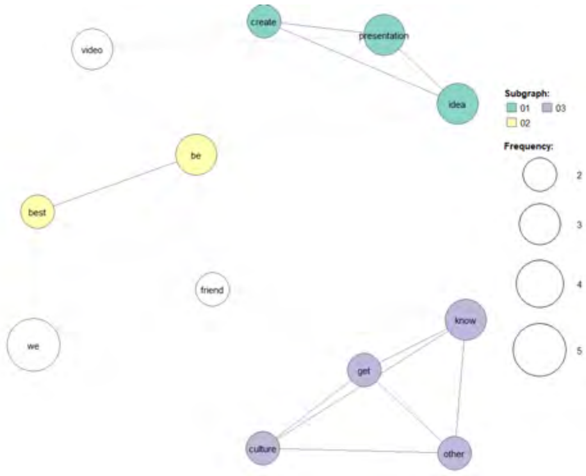

Fig.8 2020 Best experience

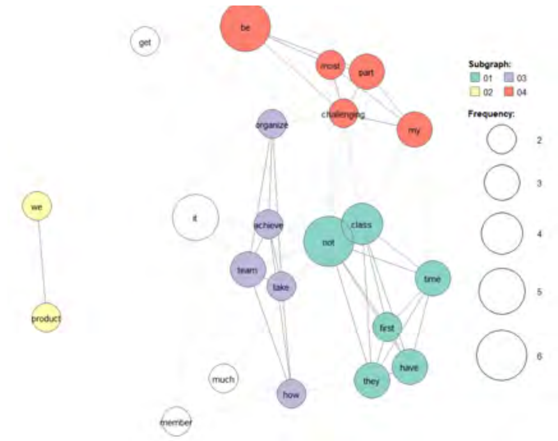

Fig.9 2020 Most challenging experience

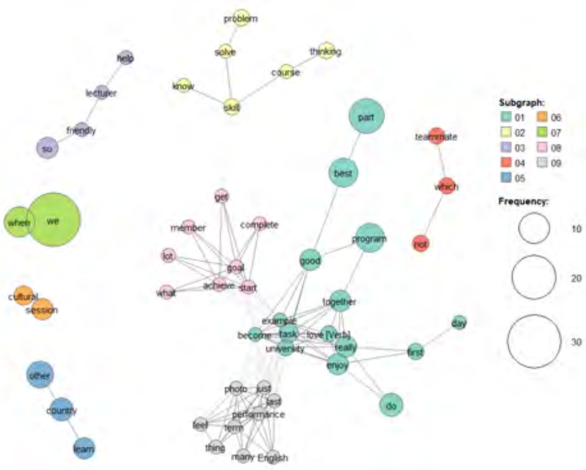

Fig.10 2021 Best experience

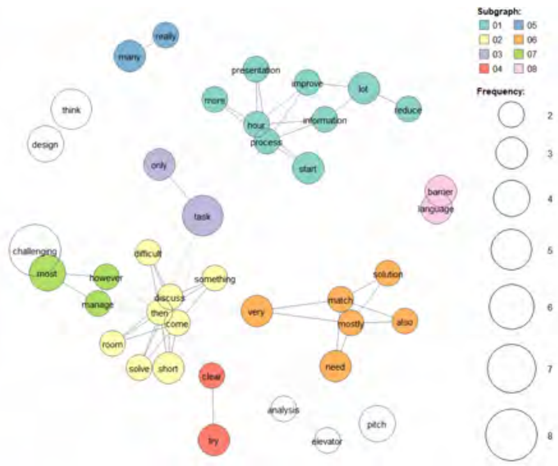

Fig.112021 Most challenging experience

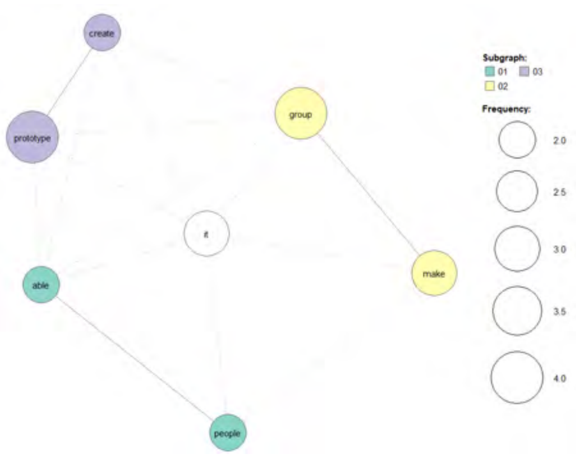

Fig.12 2022 Best experience

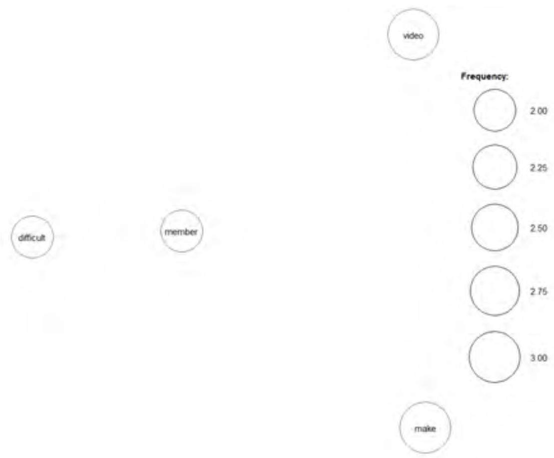

Fig.13 2022 Most challenging experience

Considering reflective statements about the quality of the learning experience brought about by GCL-DT-PBL is an excellent way to learn about the engagement of the participants. Fig.8-Fig.13 shows the co-occurrence network of participants' descriptions of their best and most challenging experiences during the 3-year program.

Commonalities were found in each year in what was interpreted through the described as the best. The participants were involved in teamwork and collaboration towards a common goal. To wrap up all the comments related to the bubbles that appeared in the analysis results above:

- 2020：The teamwork in idea creation led to the final presentation.
- 2021：Participants communicated and accomplished tasks together. They got to know each other better and better in working on the job.
- 2022：The group work allowed the participants to make prototypes and final presentations, make friends, and create something as a group.

The most challenging aspects and familiar to all years were: communication in English, teamwork, and time constraints. There were no descriptions of the degree of difficulty of the program itself. Here are some excerpts of KWIC concordance:

- I experienced how difficult communicating with other language people in English . Maybe , i did not speak correct English , but I was so enjoyed !!!
- This is the most challenging part because I am not better English speaker
- Video making as it was hard to communicate with group members thru online to get ideas
- To find the suitable time for all my groupmates for an external discussion and meeting to complete the work .

These results indicate that multicultural collaboration using English as the common language of communication is fun. Still, it also needs help communicating within the group for students uncomfortable with English. Some students also described time constraints, such as insufficient time to complete the task.

4 LIMITATION

As seen in the figure from the 2022 analysis, the sample size is affected by the response rate to the questionnaire. We need to improve the survey collection rate to grasp the overall response from the participants and prepare for the next program. Another limitation was the iterance of the cycle of the five stages of the Design Thinking process. The key to designing and manufacturing products and improving the products or systems requires constant *Kaizen*. Though the PBL deals with real-world problem-solving as a learning framework, we could not give the students enough time and opportunities to repeat the processes.

5 SUMMARY AND ACKNOWLEDGMENTS

5.1 Summary and Future Direction

This paper described the background of a multicultural collaborative PBL in the framework of Design Thinking conducted with the collaboration of four Asian universities. It showed the analysis result as part of an interim report of our 4-year project. The analysis mainly focused on student engagement, and content analysis methods using KH coder as a text mining tool were applied.

Findings are: The characteristics observed in GCL-DT-PBL participants over the past three years were consistent with the goals of this program. On the other hand, we also found that English may be a factor that can impede achievement.

The results of this survey support that this program was in line with the authors' common objectives. In addition, this analysis method allowed us to explore what words participants chose to describe in their responses and what could be read from the context. This helps to explore participants' thoughts that might not be picked up in a survey using the 5-point scale method.

On the other hand, the data size is relatively small because the program’s size is not that large. In addition, the nature of the post-program questionnaire collection, which depends on the students’ free will, has led to only a tiny amount of data being collected, as in the 2022 result. For example, formative evaluations could be added at several activity stages during the program to avoid this problem.

Step 1 and Step 2 of the Design Thinking Process showed a difference in perception of the problem. When cultural backgrounds differed within a team, points that seemed problematic to someone else sometimes did not mean as much to others. While the idea generation stage of Step 3 saw the most active participation, differences in viewpoints were observed again. Furthermore, during the team discussion to bridge the gap in views, there was a problem communicating this well using English, the common language. Step 4 prototyping and Step 5 testing had to be minimal effort due to the online nature of the project.

This paper can contribute to sharing two suggestions for future multicultural PBL design.

(1) Incorporate an approach from the perspective of cross-cultural understanding into program design to address real-world problem-solving.

(2) The need to make participants aware of the importance of additional linguistic efforts to bridge gaps in understanding due to differences in cultural backgrounds since English, the common language, is not the native language of all participants.

Future studies seek more in-depth research on how the participants improved their communication skills in English and, by that, improved their engagement.

5.2 Acknowledgment

This program has been partly supported by Ritsumeikan University Education Improvement Grant 2020-2023, and the author deeply appreciates their untiring support. The authors must remember the cooperation of all the students from the four universities who participated in the research. Last but not least, we authors sincerely appreciate the distinguished reviewers for taking much time and giving us constructive suggestions that helped us immensely. We hope this report paper could contribute to the SEFI community by sharing our outcome.

ABSTRACT

As humanity keeps facing grand challenges engineers are expected to be at the forefront and keep providing sustainable solutions to extremely complex problems. In the meantime, we have reached an era where technological advancement moves at a very rapid speed. That poses a big question to academia. “How should we educate engineers to ensure that they are best prepared for a complex world?”

For an engineering curriculum to remain effective and relevant frequent redesign is critical. Despite this generally agreed upon understanding, universities sometimes operate under great pressure and move into initiating curricular change without having considered how multifactorial this process can be. At the same time there are

[1] *Corresponding Author*

A. Bagiati

abagiati@mit.edu

little to no tools to help them determine institutional readiness for engineering curriculum redesign.

The Massachusetts Institute of Technology (MIT) has placed quality engineering education at the core of its mission since its founding in 1861. Since then, MIT has not only founded a great number of very advanced forward-thinking engineering programs, but has also collaborated with a big number of international governments and schools in order to guide and support their engineering curriculum change. The Abdul Latif Jameel World Education Lab (J-WEL) is a global consortium within MIT working on this exact topic. J-WEL staff are currently working with experts on said matter to develop a tool that universities could use in order to self-assess their initial readiness as well as their progress as they move on with their curriculum redesign process. This practice paper presents the first iteration of said tool.

1 INTRODUCTION

"Climate changes, water and food scarcities, a rapidly expanding population with longer life expectancies, increasing migration and displacement, looming threats of terrorism and nuclear deployment; are all posing mounting challenges for contemporary and future engineers" [1] Within this context, as humanity keeps facing grand challenges, engineers are expected to be at the forefront and keep providing sustainable solutions to extremely complex problems.

Although we live in a world of rapid technological development that often provides great solutions, this may come with a cost. Development in the field of Artificial Intelligence (AI) for example is expected to provide multiple solutions to these challenges and affect an increasing range of professional sectors, however "potential impacts of AI indicate both positive and negative impacts on sustainable development" [2]. In 2020 Vinuesa et. al. performed a first systematic analysis on "how AI can either enable or inhibit the delivery of all 17 goals and 169 targets recognized in the 2030 Agenda for Sustainable Development", and concluded that "AI may act as an enabler on 134 targets (79%) across all SDGs, generally through a technological improvement … However, 59 targets (35%, also across all SDGs) may experience a negative impact from the development of AI" [2]. Truby also points out how big tech's unregulated roll-out of experimental AI poses risks to the achievement of the UN SDGs, "with particular vulnerability for developing countries." [3]. Furthermore, when examining the future of work, "nearly all experts agree that machine learning, AI, and workplace automation following developments in these fields will replace many jobs worldwide" [4], while the COVID-19 crisis has only accelerated this transition.

1.1 Skills for the future

There is no doubt that today's workforce will need to learn new skills and to learn how to continually adapt as new challenges emerge and new occupations become critical. Defining the most desirable skill set while also designing educational reform and supporting sustainability is a hot topic of discussion among many academic and professional communities. According to Sarma and Bagiati while "fundamental scientific and technical knowledge is always vital, the development of such competencies as leadership, technical communication, cross-cultural communication, project management, leadership, team work, and problem solving are becoming more sought-after skills in the job market [5].” In the meantime, “as the world moves toward a digital economy, work is becoming more digital, remote, collaborative, and international” [5] while international virtual teams form and disband faster than ever. Examining the same topic, research by the McKinsey Global Institute [6] has looked at the kind of jobs that will be lost, as well as those that will be created, and it has inferred the type of high-level skills that will become increasingly important. According to their analysis the need for manual and physical skills, as well as basic cognitive ones, will decline, but demand for technological, social and emotional, and higher cognitive skills will grow. One more analysis was conducted by J-WEL. Over a period of two years, researchers analyzed 41 skill-related published frameworks and interacted with over 40 faculty, staff, and thought leaders [7]. From their research derives the J-WEL Matrix below (Figure 1).

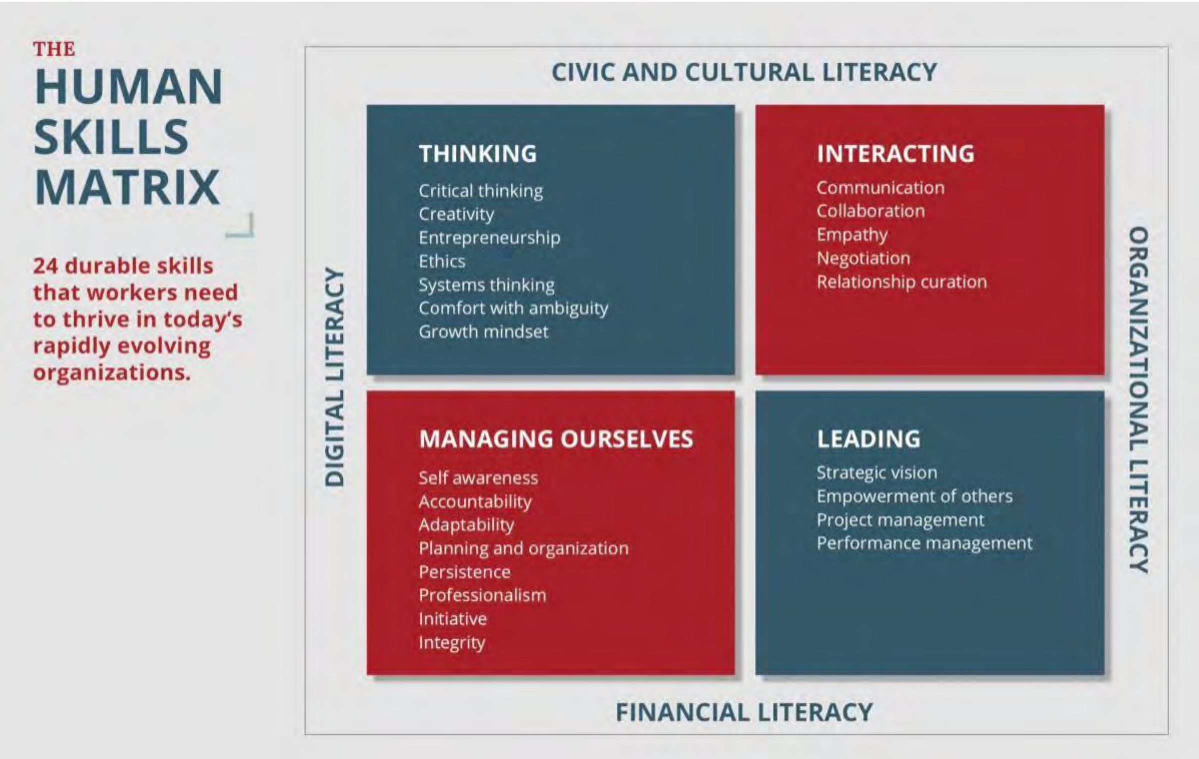

Fig. 1. The MIT J-WEL Human Skills Matrix (https://jwel.mit.edu/human-skills-matrix)

Within this context it is now critical for academic institutions to graduate students who can address the grand challenges of today and tomorrow with sustainability being at the epicenter of their academic philosophy. That will require updated curricula and employment of new pedagogical methods to best support this goal, and also the involvement of multiple stakeholders that will need to support this mission.

2 SUSTAINABILITY AND EDUCATIONAL TRANSFORMATION AT MIT AND BEYOND

MIT addresses issues and topics of sustainability and grand challenges through a variety of different platforms and approaches. One such approach is the MIT Office of Sustainability. By utilizing the campus as a testbed and incubator, this office aims “to transform MIT into a powerful model that generates new and proven ways of responding to the challenges of our changing planet.” [8] Relevant to engineering curriculum, the Office of Sustainability supports multiple sustainability minors (defined in the US as a secondary area of specialization beyond a college major degree program) that are multi-disciplinary and works to ensure that sustainability is fully integrated into teaching. Another initiative towards the same direction is the establishment of the New Engineering Education Transformation program, where students from various majors collaborate in highly multidisciplinary teams to work on authentic problems. The ideas of sustainable development are clearly rooted within the Climate and Sustainability program thread.
Educational innovation has always being at the heart of MIT, in order to promote excellence and transformation in education at MIT and worldwide. In 2017 the Abdul Latif Jameel World Education Lab (J-WEL) was launched as a joint initiative between MIT and Community Jameel. This consortium engages with global partners through a membership program. The majority of members are universities from across the globe that are addressing a specific challenge or goal they have within their own campus. In specific cases, the work of members may warrant a larger custom project that will engage J-WEL staff, MIT faculty and the members. Goal of the members is very often course and curriculum design as well as change of management and systems thinking within their higher education institutions.

2.1 Readiness Assessment Tool

While working with multiple members for years it has become obvious to the J-WEL team that member institutions often lack the understanding of how complex and multifactorial the process of redesigning an engineering curriculum can be, in order to successfully address all aforementioned needs. At the same time, when conducting a literature review there was little to no information at all regarding preparing and guiding an engineering school through the curriculum redesign process and the necessary organizational change process, especially one that would reflect state of the art educational needs. With this gap in mind authors engaged into the design and testing of a tool that could introduce member universities to all factors deemed essential during their curriculum redesign journey, that could also be used by them as a self-assessment mechanism helping them to track progress.

3 METHODOLOGY

3.1 Designing and Testing the Readiness Assessment Tool

Authors of this paper based the first development on two documents. First is the Sarma and Bagiati paper [5], commissioned by the National Academies of Engineering, discussing equity needs for the future and presenting 10 current pathways to innovation in STEM education (Table 1.) The second paper is a very detailed presentation of the development of a tool measuring organizational readiness for curriculum change in the medical field [9]. Authors adapted the aforementioned tool, specifically in terms of the critical factors, in order to reflect current needs in engineering education, and then asked five experts to go through each item presented in the tool and rate it according to their perception of importance during the process of engineering curriculum redesign (with 1 being the least important factor and five being the most important factor), as well as providing additional recommendations about factors they consider critical. The panel of five experts consisted of two MIT faculty and one program director all with extensive experience in developing engineering schools and programs, and two faculty from institutions that have collaborated with MIT in the past when designing/reviewing their engineering curriculum.

Table 1. Innovations in STEM Education [5]

1. Applying Active Learning Pedagogies	2. Implementing Competency Based education
3. Adopting a Multidisciplinary / Integrative Approach	4. Supporting beyond classroom learning experiences
5. Providing flexible, cost-efficient educational paths to continuous learning	6. Enhancing Inclusive Entrepreneurship and Innovation
7. Providing advanced support mechanisms for educational research and development	8. Developing new credentials.
9. Support connections with K-12 and peer learning/mentoring	10. Enhancing sharing and dissemination of information

4 RESULTS

Table 2 presents the organizational readiness assessment tool as well as the mean score as provided by the five experts for each category of the tool. The first two questions do not have a score, but developers think that these are questions important to clarify and consider at the beginning of the process, as they also guide the curriculum redesign process. It is expected that different countries follow different top-down or bottom-up approaches when it comes to topics such as introduction of educational innovation. Furthermore, depending on the country, there may be different governmental influences in academia.

The scale used was 1-5, with one being the least important factor and five being the most important factor (factors scored below were considered more important the closer they are to 5). Those ranked as being the most important factors by our expert respondents include ‘Focus on training students on professional/soft skills’; ‘University leadership is supportive of the curricular change’; and ‘Faculty and teaching personnel duties are clearly aligned to the goals of this change’.

Table 2. Organizational Readiness Assessment Tool for Engineering Curriculum Redesign.

Theme	Factors	Expert Score
Pressure to Change initiated from the	1. University Leadership 2. Faculty 3. Government 4. Students 5. Industry 6. Community 7. Alumni	
Necessity to Change	1. Future of work 2. Grand challenges that need to solved	
Appropriateness	1. The new curriculum will focus on training students on professional/soft skills 2. The new curriculum includes real life problems as identified by the community/industry 3. The new curriculum is guided by the latest findings of the science of learning 4. The new curriculum will focus on training students for state-of-the-art technical skills 5. The new curriculum aligns with requirements as stated by local accreditation mechanisms	4.60 4.40 3.83 3.80 3.75
Management & Leadership support	1. University leadership is supportive of the curricular change 2. University leadership is willing to provide time to staff and faculty involved in the curriculum change process 3. Government is supportive of the curricular change 4. University leadership has effective systems in place to support the change 5. University leadership is willing to provide resources 6. Government has effective systems in place to support the change.	4.80 4.20 4.00 3.80 3.40 3.40
Staff culture: Faculty and teaching personnel …	1. ...are willing to innovate and/or experiment to improve teaching 2. ...cooperate to maintain and improve effectiveness of teaching 3. ...feel a sense of personal responsibility to improve teaching and learning 4. ...are ready for co-teaching a multidisciplinary / cross-disciplinary course	4.40 4.40 4.40 4.25

	5. ...discuss this change with each other in both formal and informal situations 6. ...work together as a team 7. ...are receptive to changes in the curriculum 8. ...share responsibility for the success of the curriculum redesign 9. ...university leadership has effective systems in place to support the change 10. ..are ready for co-teaching a traditional course	4.20 4.20 4.20 3.80 3.80 3.50
Formal Leader of this Innovation…	1. ...accepts responsibility for the success of this project 2. ...cooperates well with the both university leadership, faculty and teaching personnel 3. ...has the authority to carry out the implementation of this change 4. ...has been identified	4.40 4.20 4.20 4.20
Key stakeholders involved	1. Have all stakeholders been identified? 2. Have all stakeholders been involved?	4.20 4.00
Project Resources	1. Faculty and teaching personnel training on new content 2. Faculty and teaching personnel awareness of this change 3. Evaluation mechanism 4. Faculty and teaching personnel training on new pedagogies 5. Expert staffing 6. Facilities 7. Equipment and materials 8. Financial resources	4.40 4.40 4.20 4.20 4.00 3.80 3.40 3.40
Clarity of Missions and Goals	1. Faculty and teaching personnel duties are clearly aligned to the goals of this change 2. Curriculum developers presented clear goals and objectives regarding the new curriculum 3. Faculty and teaching personnel understand how the change fits in with the desired competencies of learners	4.60 4.40 4.20
Implementation Plan	1. ...acknowledges faculty and teaching personnel input and opinions 2. ...includes appropriate training 3. ...includes a plan for improvement based on recurring evaluations 4. ...identifies specific roles and responsibilities 5. ...describes tasks and timelines	4.20 4.20 4.00 4.00 3.80

FUTURE WORK

Authors are currently incorporating additional expert suggestions, and will first share the tool with J-WEL's university-members who are currently working on curriculum development and reform, receive further feedback from members, and use this opportunity reiterate and improve the tool. Particular attention will be paid in order to identify cases in which what the tool suggests may be counter to local legislations, conditions, academic cultures, and protocols. Members are expected to use this tool when they will start planning their curriculum design/redesign, but also use it for regular check-ins throughout the process to identify and measure progress.

Following this stage, authors will make the updated version of the tool open and useable for all and share widely via the J-WEL website.

Furthermore, there is opportunity for future work by sharing this tool with policy makers and determining if it may influence the way they design educational policy and how they might support and encourage academia partnerships with local communities and the industry.

***Conference Key Areas**: Engineering Skills and Competences, Fostering Engineering Education Research*
***Keywords**: autoethnography, narrative, community of practice, ethics education, Eastern Europe*

ABSTRACT

Representation of diverse people's perspectives, cultures, and ideas enriches societies. Equally important for communities to flourish is to have diverse perspectives on what good ethics education is. For 50 years the European Society of Engineering Education (SEFI) has been uniting and supporting engineering educators and researchers from around the globe and particularly from Europe. However, involvement from institutions in Eastern Europe is still very low. To diversify and strengthen the community by bringing perspectives from these countries, we engaged in an autoethnography study to share insights on participation barriers broadly and ethics education, more specifically. We choose autoethnography as this methodology allows researchers not only to share their own experiences but to connect in making meaning of a phenomena and to form a community of practice. The researchers and authors of this paper are representing STEM institutions in three Eastern European countries. Applying an interactionist approach, we engaged in a community of practice group to discuss the current state of the art of ethics education in our own institutions and to talk about the experiences with ethics education, academic integrity, and ethics culture. We collectively selected an appropriate framework and applied that framework to interpret the findings. Transcripts were analysed by all five researchers. The paper and the presentation will be presented together as a narrative story. The goal of this work is to form a community of practice and to create an agenda to engage the newly formed community of practice with the broader SEFI ethics education community.

1 INTRODUCTION

1.1 Motivation

The EU STEM Coalition is an EU-wide network supported by the Erasmus Programme that works to build better STEM (Science, Technology, Engineering, Mathematics) education in Europe. The European Commission (2020) claims that in most EU countries there is a shortage of educators across all fields of study, and particularly in STEM disciplines. Moreover, the report claims that educators need continuous opportunities for professional development, teaching in multilingual and multicultural classrooms, and opportunities for cooperation between higher education institutions [1]. The report further suggests that international mobility of students and educators must become part of educators training to broaden the access to the diversity of quality teaching approaches [1].

The communication report sets an agenda to be reach by 2025 with major focus on objectives such as: 1) *connectivity* among higher education institutions and with their surrounding ecosystems and society; 2) *inclusion* to ensure accessible higher education institutions, open to a diverse student and researcher body; 3) *integration* of learning and training for sustainable development across all disciplines through an interdisciplinary and challenge-based approach, where innovation is an important component.

At the heart of all the above objectives, representation of diverse people's perspectives and ethics education considering all stakeholders and State Members, are regarded as the essence to build better STEM education in Europe.

Educational innovations, connectivity, inclusion, and integration, including best practices in teaching, as researchers suggest, happens more quickly through direct connections between people rather than dissemination through the literature [2]. In coordinating STEM ethics education community level support efforts to include diverse representation of scholars across Europe, is to develop a Community of Practice (CoP) to foster connections between educators and researchers. Utilising an autoethnography study, this narrative paper aims to synthesise the experiences in teaching ethics of five scholars who are interested in forming a CoP. A CoP can have a variety of structures and it can be formed and run explicitly by members or can have external facilitators. The meetings can vary from explicitly virtual, hybrid or in-person, only a few times a year to multiple times per month, and they can be implemented on any scale, from international to unit-level [3].

While in some CoPs, incentivization for CoP members is formally recognized by an organisation, in our CoP as in many other CoPs, members have an intrinsic motivation to engage in CoP as the opportunity to network, learn from each other, and to engage in professional development [4-7]. Particularly, members in our CoP benefit from the common values of CoP structure, such as having a space for us to come together and collaboratively work on challenges, while also providing safe spaces for members to reflect on their own practices. CoPs allow members to easily access the collective knowledge and expertise of the group and to rely on others for professional or emotional support [7]. Further, to sustain our newly formed CoP, we plan to meaningfully coordinate resources and the accumulation of collections of knowledge and best practices. These benefits position our CoP as a powerful mechanism for supporting and sharing educational innovations, connectivity, inclusion, and integration as set by the European Commission agenda for Achieving the European Education Area.

1.2 Theoretical Framework

The foundation of the CoP framework is based on the Situative perspective on learning where social interaction is essential for our learning and knowledge-gaining [3]. According to Wenger and colleagues, CoPs have three elements: *domain* of interest (knowledge and problem focus) they are centred on, *community* of people that comprise the group, and *practice* that members share and innovate around [3, 4]. Applying an interactionist approach, the authors of this work reflect on the current state of the art of ethics education in our own institutions and chose to engage in a CoP to improve our practice with the support of others by providing a structured group environment that allows for strong connections to form [4].

2 METHODOLOGY

2.1 Autoethnography

Autoethnography is a qualitative method approach that helps researchers to describe and systematically analyse personal experience to understand cultural experience [8]. The researcher blends autobiography and ethnography, engaging in a method that is both the process and the product. To construct the narrative, the facilitator of our CoP developed open-ended reflective prompts with the intention of providing enough scope and context to yield responses that capture different perspectives on similar experiences. As Wenger [4] emphasises the domain of interest, the community, and the practice are the essential elements of a CoP, our prompts progressed through the stages of exploration of the domain of interest of ethics education (why and how to teach ethics); our own lived experience (our role in teaching ethics), and lastly, meaning making through the CoP to develop and maintain the CoP core knowledge.

2.2 Data Analysis

The interactions approach builds upon the co-creation of the narrative. The narrative-inquiry autoethnography approach allowed the researchers, as a group, to examine significant experiences from our own perspectives having lived through them. The narrative inquiry and reflective writing allowed us to write about our own experiences to generate a data set for analysis and meaning making to present our collective views as a community of practice. Qualitative thematic analysis was used to iteratively generate common codes, to then be grouped around common themes as the main areas of interest for this work.

Our autoethnography method involves the following process: firstly, the facilitator posted four prompts on shared space where all authors have secured access to the file. Authors, then independently in the form of narratives addressed the prompts. All authors were able to see each other's responses as the narratives were evolving. Secondly, the facilitator coded through an inductive thematic analysis all narratives for initial emerging themes. Thirdly, the narratives were coded by each author individually. The authors then built consensus and merged their individual code lists and created a unified codebook before conducting a second iteration of individual coding. Key themes (meaning making) were identified from groupings of the final code list to inform the analysis. The final analysis and key themes are presented in this paper.

2.3 Rigour and Trustworthiness

Autoethnography often is criticised by the research community as being self-indulgent and not sufficiently rigorous, however, scholars from multiple disciplines argue that there should be and there is a place for research that links the personal with the cultural. Some researchers suggest that autoethnography can encourage empathy and connection beyond the self of the author and contribute to sociological understandings [9]. In this co-created narrative, we autoethnographically linked personal experiences of implementing ethics education in the STEM curricula and being included in the larger SEFI community with pertinent issues reflective of research culture to contribute to understandings of challenges of participation and inclusion in the SEFI community. It is up to this larger community and gatekeepers of research to allow the sharing of perspectives and with a variety of research methodologies and styles of representation. The findings of our autoethnography study could be compared with findings from the broader literature on STEM ethics education and Community of Practice. That comparison could be an evaluation criterion of rigour and trustworthiness, of course considering the phenomenon of the lived experiences and cultural backgrounds.

3 RESULTS

The initial key ideas and impressions emerging from the reflections were grouped and organised into thematic sections by the facilitator of the CoP, resulting in twelve emerging themes. Then the narratives were coded by each author individually and consensus to merge their individual code lists was reached. Sixteen key themes (meaning making) were identified from groupings of the final code list to inform the analysis. The final analysis and key themes are presented in Table 1 below, organised in an order of the four prompts: 1) why should we teach ethics; 2) how should ethics be taught; 3) what is an educator's role in teaching ethics; and 4) how do we deepen our understanding of ethics education through community.

Table 1. Key themes from the four prompts and meaning related to CoP

Prompt	Themes	Meaning related to CoP
Why should we teach ethics?	Prepare students for post-graduation **success**. Allow students to develop **critical thinking skills**. Help students become **better decision-makers**. Support students' **development of academic, social, and emotional competencies**. Introducing students to **emerging areas in STEM** - AI and robotics that raise **new ethical questions** are rather different from other engineering disciplines. To make students understand the impact (**risks, outcomes etc) of professional activity** in a broader, societal context.	Domain and interest of the CoP members

How should ethics be taught?	**Theoretical foundations** in **moral** and **ethics** education. **Case studies** - a balance between explaining why and demonstrating how. To elicit **moral emotions** and hence intuitions to see how reliable these are for **our shared living** within the academic community.	Expertise and practice Learning from each other Identification of best practice examples
What is my role in influencing the adoption of ethics in the curriculum?	**Role-modelling**. **Historical** and **cultural** influences. Identification of emerging issues connected with **new technology applications**.	Challenges Resources
How do we deepen our understanding of ethics education through community?	**Value-added** – intrinsic motivation to participate in the CoP. **Belonging** to a community with similar backgrounds (geographical, historical, and social). **Resource sharing**. **Common activities**, seminars, and exchanging experiences.	The benefits of Community of Practice

The largest number of themes (6 themes) emerged from the responses to the first prompt - *Why should we teach ethics*? These themes were linked to the specific STEM domain as well as the professional interest of the CoP members. A couple of quotes, provide a description of the themes in this prompt - "*Teaching Ethics is not about teaching Ethics. It is about teaching how to see your professional activity in a broader context. Engineers, executing their professional tasks, serve society."* and "*There are many reasons for teaching ethics, ranging from those related to the moral and social development of each student to those related to the wise governance of technology and its implications*."

There were three key themes emerging from responses to the second and third prompts, respectfully - *How should ethics be taught?* and "*What is my role in influencing the adoption of ethics in the curriculum?*". The following quotes represent descriptions of the themes in these two prompts: "*What works best is a brief theoretical introduction followed by real life examples related to the theoretical part. Then we apply a problem-based approach when we present a list of problems (in advance)…Of course, with new technologies there will be new questions that will probably need* *different approaches*." and "*taking a pensive stance, arguing how to assess its design, affordances and functionalities from a moral and epistemic perspective…the first goal is to elicit moral emotions and hence intuitions in order to see how reliable they are for our shared living within the academic community. Then we proceed to see the intricate relationship between those intuitions, i.e., beliefs, and the moral values, principles and norms that ground our communal existence."* These themes in the second prompt are linked to the expertise and practice of the CoP members, as well as an opportunity to learn from each other and identify best practice pedagogical examples.

The themes in the third prompt were linked to the opportunities of the CoP members to share challenges and resources, including helping students to feel belonging to the larger community of STEM ethical practitioners - *"My role, and that of my colleagues, would be to maintain a strong interest in the field, an interest that stems primarily from the practical nature of ethics in assessing everyday situations and making informed decisions, thus creating a positive social output. I recognise that the professional role of ethics is rather secondary for undergraduate students and is given more attention as an exercise in discovering and growing moral virtues to better situate themselves in the world of technology, not just as users but as creative agents. For students, I prefer a mix of personal exploration and ethics as a tool for professional endeavour."*

The last prompt in this authoethnography study was "*How do we deepen our understanding of ethics education through community?*". Addressing this question, the authors of this paper individually identified the benefits of forming and participating in CoP and then collectively agreed on these benefits (meaning making). The following quotes best describe the key themes in this category: *"This sense of belonging can be reinforced with reference to ethical questions within other courses and disciplines. Evidently, increasing interest in research on ethics can also contribute to an increase in the interest and awareness on the subject in our institutions." and "We can also try to identify a call for projects (e.g., in Horizon Europe) that corresponds to these ideas. In addition to the professional part, we should introduce the topic to the broader public.*"

4 SUMMARY

As the initial work for establishing a Community of Practice is completed through the process of writing this conference paper, we plan to sustain the group by creating more networking opportunities starting with monthly meetings in the coming academic year. We plan to expand the group and create a space where we can share teaching resources (videos, assessment rubrics). We further plan to engage with the CoP with invited talks, seminars in each other's universities and at conferences, with the goal of establishing collaborations to complete studies together, publish, and eventually apply for funding to work on joint projects.

Sustainable Development of the Budapest University of Technology and Economics (BME), Faculty of Economics and Social Sciences (GTK), has developed a unique method for a uniform certification of studies in the fields of sustainability, environmental economics, and environmental management for engineering students. The so-called green certificate is provided after the successful completion of at least five elective courses such as sustainable business models, green economic development, smart and sustainable digitalisation-related solutions, sustainable rural or urban development, sustainable energy management or climate change oriented courses etc. The certificate can be obtained either in the framework of a bachelor's or master's degree programme, and it is available both in Hungarian and in English, even for incoming mobility students. By achieving the green certificate, the engineering students gain a complex vision, a sustainability mindset and a truly green attitude. Our study analyses the green certificates' data quantitatively, focusing on the engineering students' profiles and the most frequently chosen courses. Our results can help further refine our methods to reach even more engineering students, and it can serve as a good practice to follow for other universities.

1 INTRODUCTION

1.1 General Introduction

Engineering plays a crucial role both in addressing sustainability challenges and in helping to achieve the sustainability transition. However, tackling the complex problems of our time requires expertise from multiple disciplines, as social, environmental and economic challenges are often not only impossible to understand but also impossible to solve using a single perspective or knowledge framework due to their complexity (James Jacob 2015). Engineering practice has also become more and more multidisciplinary in the last decades (Lattuca et al. 2017). Engineering education, therefore, needs to be complemented with knowledge from non-engineering disciplines to address complex problems, and a holistic pedagogical approach has to be applied (Kövesi et al. 2021). The main aim is to train students who are sustainability literate (Sterling and Thomas 2006) and have the competences needed to solve sustainability challenges (Bianchi 2020). As university curricula are structured by disciplines, the application of inter-, trans- and multidisciplinary approaches is not a clear and easy process, especially in engineering education. Even though these methods share the same fundamental ideas, there are major differences between them. Interdisciplinary education requires multiple disciplines to create a synthesis of their knowledge and methods, transdisciplinarity constructs an intellectual framework that is unified beyond disciplinary perspectives, while multidisciplinarity is a more individual approach where the joint efforts involve the juxtaposition of different disciplinary viewpoints (Stock et al 2011; Marques 2008). These methods encourage the capacity to comprehend complicated issues and take appropriate action, which is consistent with the aims of education for sustainable development (Annan-Diab and Molinari 2017). Sustainable practices are often integrated into engineering programs by either creating or offering stand-alone courses added to the curricula or by integrating them into one of the already existing courses (Mesa et al.2017). These approaches are essential in reshaping engineering education to complement the engineering skillset with competences form other disciplines, such as management and social sciences thus preparing the engineering students to understand and solve complex problems from different perspectives.

1.2 Green Certificate

The Green Certificate is a great example of providing complex sustainability knowledge in a multidisciplinary learning experience for students of engineering and natural sciences. It is an initiation of the Department of Environmental Economics and Sustainability at the Budapest University of Technology and Economics Faculty of Economic and Social Sciences (BME-GTK).

The Green Certificate is not an accredited diploma, it is a supplementary verification of completed sustainability management courses. It has more than 30 years of history starting in the early 90s. Former students asked the department about the possibility of some kind of recognition of their sustainability-related studies to be used in the labour market. The department developed the green certificate as a response to this request. To obtain a green certificate the students have to complete at least five of the courses advertised and taught by the Department of Environmental Economics and Sustainability during their studies as elective courses. This can be done either during the bachelor's or master's degree course or during the two courses together. The courses are available in both English and Hungarian, therefore international students can also participate. The completion of English courses can be a good preparation for Hungarian students as well to support the preparation for studying abroad or for multilingual jobs (multinational companies, EU institutions). There is a broad portfolio of subjects available including the fields of corporate environmental management, climate change, sustainable regional development, sustainable business models and EU environmental policies, etc.

Students from all educational programmes at BME can apply for the certificate, the only exceptions are students from the Master’s in Regional and Environmental Economic Studies and the Master’s in Environmental Engineering specialization of Environmental Management, as their compulsory core subjects include already the required courses. After the completion of the five elective courses, the students have to request the green certificate by filling in a simple online form on the Department’s website. Each semester the department organizes a graduation ceremony where the green certificates are handed out. The actual green certificate provides information in both English and Hungarian on the number of hours and courses in environmental economics and management that the holder has completed. The green certificate is a tool for conscious career development, since based on the informal feedback of former students, the certificate can be an advantage in job applications.

2 METHODOLOGY

The main objectives of this practice paper are to provide a quantitative analysis of the Green Certificate based on the related administrative data from the last five years - between 2018-2023. The aim of our paper was two-folded, firstly to showcase this successful local best practice on how to integrate a multidisciplinary educational approach into the engineering programmes, and secondly, to formulate recommendations for future developments based on the data analysis. The methods used for the quantitative analysis are descriptive statistics and exploratory data analysis. We built our conceptual framework based on existing literature summarized in the introduction part about the importance of multidisciplinarity in education. The actual data for the analysis were retrieved from Neptun, the online educational administration system that holds all academic data and personal information of the students. We focused on the frequencies and percentages related to the participating students, and their chosen courses, and we used graphical display methods to present the results. Based on the lessons learnt we formulated recommendations for further improving the impact of the program.

3 RESULTS

As it was previously mentioned, the retrieved data covered 5 years starting from June 2018 till March 2023. During these years and months, all together 909 students completed successfully the requirements and applied for the green certificate. Fig. 1. shows the number of certificates per academic year, and it only counts with 859 certificates, as 50 certificates were obtained before September in the academic year of 2018/19. The data for the 2022/23 academic year is not yet complete. The key finding is that COVID-19 did not have a negative effect on the number of green certificates issued, the opposite is true: most certificates were issued during the two worst years of the pandemic (2019/20, and 2020/21). There is a significant fallback in the number of certificates in 2021/22 by almost one-third. Further investigation is needed to discover the potential reasons behind the fallback and the final results of 2022/23 should also be added to see whether the decline is continuing.

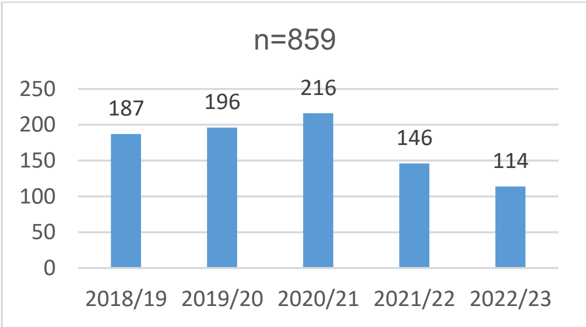

Fig. 1. Number of issued Green Certificates for 5 academic years

Fig. 2. shows the ratio of different fields of study among those 909 students who obtained their certificates between June 2018 and March 2023. More than 60% of the students study engineering, and 31% have a management background. There was only one PhD engineering student, and one from natural sciences giving less than 0,3 % of the total throughout the 5 years. The key results from these data are to increase the number of students participating in the Green Certificate program from the Faculty of Natural Sciences, and also potentially PhD students from any faculties.

We were also interested to see which level of study is represented the most among the participating students (Fig. 3.). The results mostly matched our expectations, as the majority of the students belonged to bachelor-level studies, however, it is surprising how much higher the ratio is – a little more than 92% (almost 62% engineering, and 31% management students), whereas only 7,5% students studied at master level among the participating students. There are much more bachelor students at BME than master students, however, there is a place for improvement in recruiting more master-level.

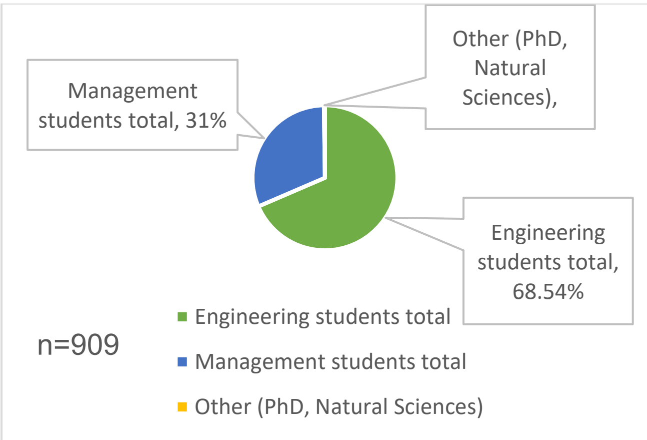

Fig. 2. Ratio per Fields of Study 2018-2023

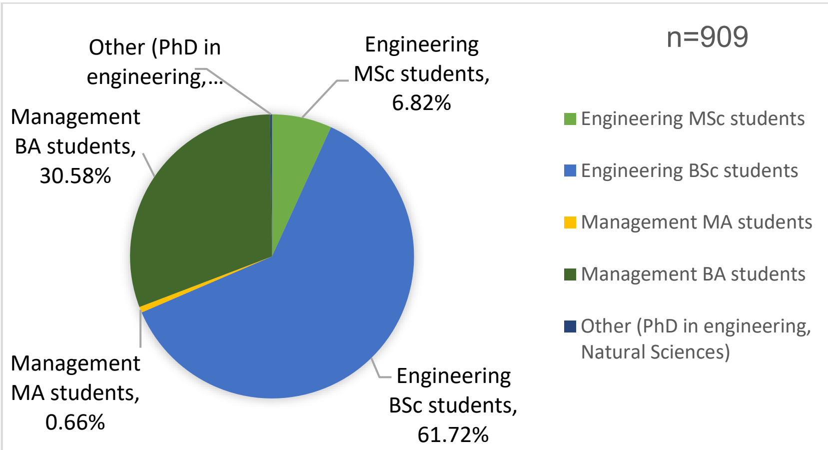

Fig. 3. Ratio of level of studies among those awarded with Green Certificates between June 2018 and March 2023

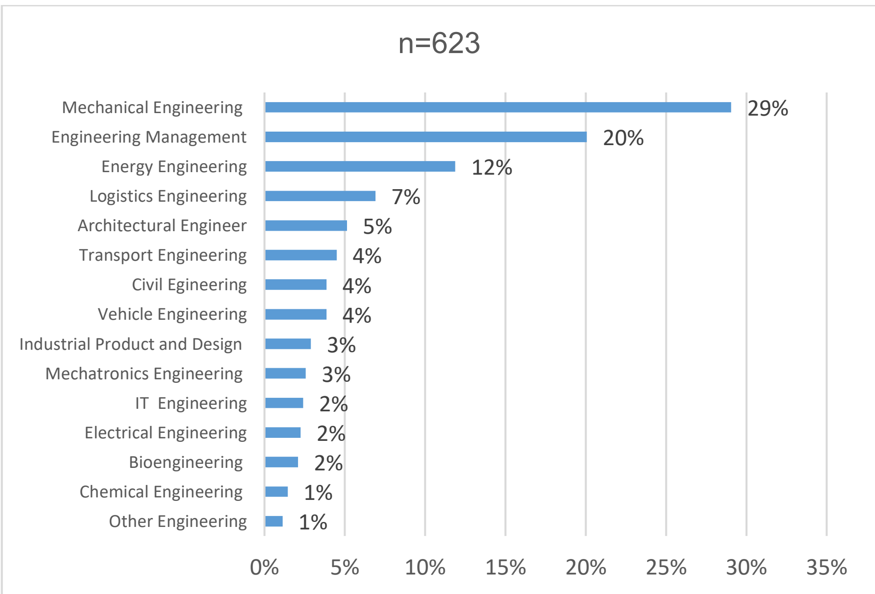

Fig. 4. Different fields of study of engineering students

All faculties from BME are represented among those who obtained the Green Certificates. Fig.4. shows the ratio of students from different engineering studies. The highest ratio of the students awarded studied Mechanical Engineering (29%) either at bachelor or master level, the second highest ratio is from Engineering Management (20%) from the Faculty of Economic and Social Sciences, the third highest is from the Energy Engineering students (12%). Some engineering fields are very underrepresented, such as Chemical and Bioengineering (1% and 2%) and Computer Science Operational Engineering (below 1%).

The international students and courses ratio in the Green Certificate program is very low. The non-Hungarian student ratio is less than 1% - there are only 8 students out of 909 who are non-Hungarians. Sometimes Hungarian students also choose courses held in English, therefore all together 71 English courses were attended out of the 4801 total course number.

Table 1. shows the top 10 list of courses chosen by the engineering and management students separately. The list is different for the two groups even in the top three places. The most popular course in both cases is Environmental Economics. The course Waste Management is also widely chosen by both groups, it is in second place for engineering, and third place for management students. The third place for engineering students is Environmental Management, while Strategic Planning of Climate Protection is the second place for management students. This latter course is completely missing from the list for engineering students together with the Sustainable Business Models course. Climate Change – Advanced level, and the Environmental Management Systems courses are missing from the management students' list but appear on the engineers' top ten list. The courses that appear in both lists but in different places are Environmental Law, Environmental Practices in Energy Management, Environmental and Regional Policy of the EU, Regional Economics, and Human Nature vs. the Natural Environment.

Table 1. The 10 most popular courses among engineering and management students

Engineering Students n= 3268		**Nr.**	**Management Students** n= 1512	
Environmental Economics	16%	1	19%	Environmental Economics
Waste Management	15%	2	13%	Strategic Planning of Climate Protection
Environmental Management	10%	3	12%	Waste Management
Environmental Law	8%	4	11%	Regional Economics
Climate Change – Advanced level	7%	5	11%	Sustainable Business Models
Environmental practices in energy management	7%	6	7%	Environmental Management
Environmental and Regional Policy of the EU	6%	7	5%	Environmental Law
Regional Economics	5%	8	5%	Environmental practices in energy management
Environmental Management Systems	4%	9	4%	Environmental and Regional Policy of the EU
Human nature vs. the natural environment?	4%	10	3%	Human nature vs. the natural environment?

4 SUMMARY AND ACKNOWLEDGMENTS

In this practice paper, we have overviewed the Green Certificate program. We examined with quantitative methods through descriptive statistics and exploratory data analysis the data from the last five years (2018-2023). We have seen that the Green Certificate is widely known among the students of the university, during the 5 years more than 900 certificates were issued providing sustainable management competences to engineering and management students. In conclusion, we can say that the program is indeed successful as a multidisciplinary approach for sustainability competences among engineering students. The weakest points are internationalization and involving master and PhD level students. There are a lot of similarities in what topics engineers and management students consider important, but there are significant differences as well that could be addressed when planning and designing the available courses. Overall, this model is suitable to be implemented in other universities as well.

The limitations of our research include its presentation solely based on the data available from our administrative system. It was beyond the scope of this paper to conduct a survey or interviews among the participants. Therefore, in the future, we plan to conduct both quantitative and qualitative research among green diploma holders to explore whether the students obtained a comprehensive sustainability mindset as a result of their studies and the impact of the green diploma on their employment.

We have formulated the below recommendations based on our results to further improve the Green Certificate program.

- A communication campaign could be organized at the university in English targeting Erasmus incoming students and regular foreign students to increase the international student participation ratio in the Green Certificate program.
- A communication campaign should also be organized for Hungarian students from the fields that are less represented in the program: natural sciences, all master and PhD level students.
- To further develop the level of sustainability integration in the engineering programme curricula, designing new interdisciplinary courses together with the engineering departments might be beneficial.
- To develop an e-badge as a digital proof of the recognized green competences that allow the students to showcase them on digital platforms. This can be a more suitable solution for the younger generations, and it can increase the popularity of the program.

This study was supported by the UNKP-22-3-II, the UNKP-22-5 New National Excellence Program of the Ministry for Innovation and Technology and the Bolyai János Research Scholarship of the Hungarian Academy of Sciences. This endeavor would not have been possible without the help of colleagues Katalin Käsz and László Valkó, PhD, who provided valuable input, insights, and assistance for this paper.

ABSTRACT

This paper addresses the students' mental health in higher education and more specifically in engineering schools. Several studies have shown student mental health

---

cathel.zitzmann@epf.fr

and wellbeing can affect students’ academic performance. We investigate how student’s mental health is considered in engineering schools as well as how it should be and study the case of our engineering school.

First, we present several research and studies conducted on how mental health is considered in higher education and its impact on academic performance.

In the second part, we study the case of our engineering school with the implementation of a survey among students and teachers to collect their feedback. We add to this survey a collection of testimonies from students. We will analyse how mental health is considered and the impact of addressing mental health on student success in an engineering school.

Finally, we present possible solutions to improve the consideration of mental health. These solutions are aimed at administrations, teaching staff and engineering school students. Indeed, the consideration of mental health must be global and concern the entire educational organisation.

---

1 INTRODUCTION

1.1 Background

Student mental health remains a subject that is not sufficiently addressed (Morvan and Frajerman 2021) in France. Currently in France, higher education institutions are not required to have indicators on the mental health of their students. Yet student ill-being is a major issue. Several studies on the emotional distress of European and North American students highlight this ubiquitous problem, less frequent in non-student populations of the same age. In 2013, 20% of 10–24-year-olds were subject to mental health problems each year (depression, anxiety). More recently, after the COVID crisis, a survey carried out by a health insurance company (LMDE) indicates that in 2022, 68% of students in France were in a situation of ill-being. 52% said that Covid had affected their social interactions with friends and family, 44% their emotional and family life. In addition, more than half of the students interviewed were afraid that their degree obtained during the health crisis is devalued.

Student ill-being is defined in our article as an unusual negative feeling, which can be a combination of sadness, anxiety, a feeling of "fatality" with a loss of interest in certain aspects of one's life. In concrete terms, a study (Boujut, Koleck, Bruchon-Schweitzer and Bourgeois. 2009) shows that this feeling of ill-being can lead to emotional distress, depressive symptoms, suicidal thoughts, a feeling of loneliness, stress, anxiety (strongly related to work and academic success, as well as time and money), obsessive-compulsive disorder or substance abuse. Another study (Gosselin and Ducharme 2017) identifies more precisely the main factors of student distress and anxiety. Distress can be triggered by fatigue or exhaustion, academic pressure, family conflict. The three most frequent symptoms of anxiety were the feeling of not being capable, the fear of failing and the fear of disappointing.

When students use the help available for their mental health, their anxiety symptoms decrease. However, the usage of support is influenced by existing bias about mental health, that reduce students' willingness to seek help.

According to the World Health Organization (WHO), mental health is "a state of well-being that enables people to achieve their potential, cope with the normal challenges of life, work successfully and productively, and be able to contribute to the community". Mental health is determined by many factors: socio-economic, biological, and environmental, including the working environment. Working conditions are indeed an important determinant of mental health.

It has also been shown that epidemics contribute to the deterioration of mental health. Students are identified as a part of the population that is particularly vulnerable to anxiety, depression, stress...

1.2 Aim and questions

Faced with this problem in their daily lives, student engineers decided to write an article on the mental health of students in engineering schools. To do this, we built a survey:

- to measure whether this is a reality in our school and on what scale.
- to evaluate the perceived impact of studies on students' well-being.
- to identify measures that have a positive impact on students' mental health.

2 METHODOLOGY

An online survey was submitted in May 2023 to all students of EPF, a general engineering school. Data were collected during a week holiday, specifying their home campus (Cachan, Montpellier or Troyes), their year of training (from the first to the fifth-year post-bac) and their gender.

The survey included both closed and open questions: 16 questions on students' general well-being, 4 questions on the perceived impact of their studies on their ill-being, 6 questions on mental health support and awareness.

3 RESULTS

Our final sample consisted of 185 responses: 85 students from Cachan, 73 from Montpellier and 27 from Troyes. We wanted to obtain representative samples from each campus because student support and infrastructures are not the same for the different campuses.

Our sample is composed of 109 men, 71 women and 5 not defined. We'll take an interest in comparing results between our men and women samples.

The five years of engineering studies are divided into two cycles. The 3-year Bachelor cycle includes two years of preparatory classes. The last 2 years (Master cycle) are devoted to one major of the nine proposed by EPF for one half and internships for the other half. 77% of the respondents to the survey are Bachelor students (143 students), the remaining are Master students (42 students). In the same way we'll compare results between the different academic years, to study the impact on mental health.

3.1 Sense of belonging

The first questions of the survey deal with the students' feeling of belonging to their environment: whether they feel they belong at school, then in their class and finally whether they feel surrounded and supported overall. Students feel that they belong in the school (77% "Totally agree" and "Agree") and in their year group (87%). Students globally feel supported and surrounded (75%). There is a disparity between campuses on this question: from 60% to 83%. Few students (5%) answered "Disagree" or "Strongly disagree" to the three questions. The students who responded to the survey generally feel that they belong at school.

3.2 Ill-being

Despite this feeling of belonging, 68% of the students interviewed answered "Yes" to the question "Have you experienced periods of ill-being during this school year?". 60% of respondents identifying as men experienced periods of ill-being during the school year. This proportion rises to 78% when respondents identify as women. Regarding the academic year, the percentage is similar for all years: about 2/3 of the respondents experienced periods of ill-being during the academic year and this reaches 80% for 2nd year students. There is also a disparity depending on the campus: from 64% to 75%.

This highlights the fact that considering the mental health of students in an engineering school is not limited to their overall sense of belonging. It is also necessary to provide support during periods of ill-being, even if they feel well for most of the year, particularly regarding the consequences of these periods.

Indeed, different consequences of ill-being were then proposed to the students who answered "Yes" (Fig. 1). We note that among these students: 63% have altered the quality or quantity of their sleep, 55% became isolated, 55% could no longer concentrate, 36% changed their eating habits, 30% could no longer manage their daily lives, 15% had suicidal thoughts, 14% had an addictive behaviour, 9% had harmed themselves.

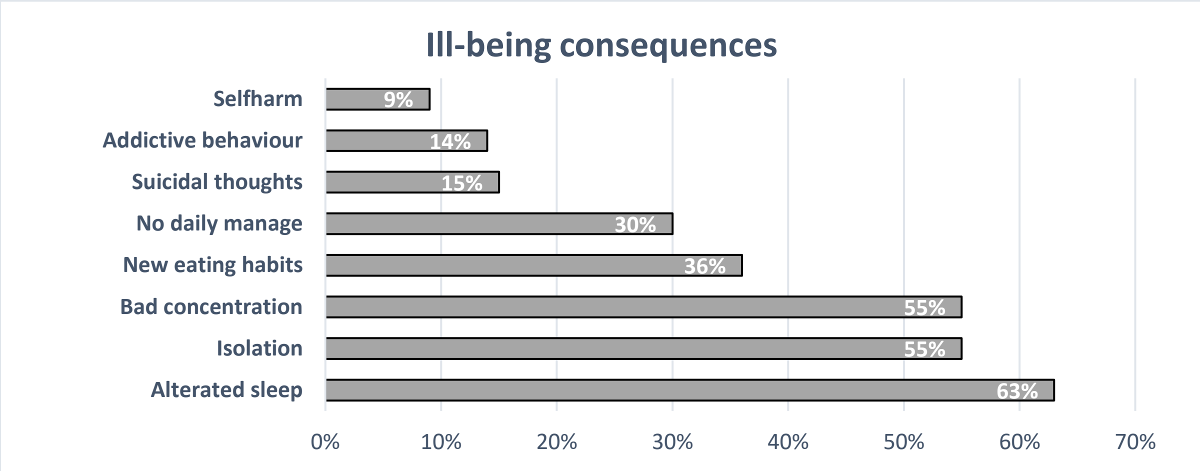

Fig. 1. Consequences of ill-being on students

70% of students who experienced ill-being felt that it was accentuated by their studies.

3.3 Stress

In the collective imagination, student ill-being is often associated with, or even equated with, stress related to academic pressure. We asked students to evaluate their stress level on a scale from 0 (no stress) to 10 (absolute unbearable stress). Levels 4 and 5 are average stress. Level 6 and beyond correspond to high stress.

When the question of stress is raised in our survey, we obtain (Fig. 2.):

- Exam period stress of 5.62/10 on average.
- Academic stress (excluding assessments) of 4.35/10 on average.
- Extracurricular stress of 4.16/10 on average.

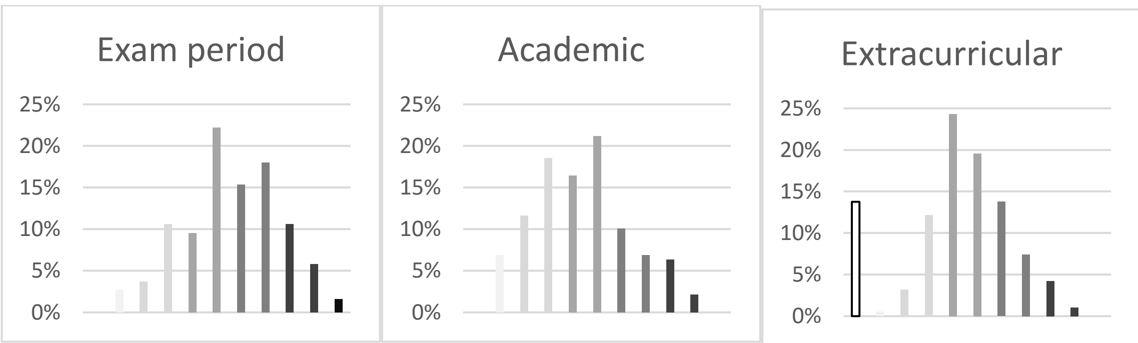

Fig. 2 Students' stress level (from 0 to 10 from left to right) distribution during (a) exam period, (b) academic time and (c) extracurricular time

Students were asked about the main stressors in their studies. The most common answer is "exams and projects reports". More surprisingly, it's not the difficulty of the work that is mentioned next, but the time management. Indeed, the overlapping of different exams and reports deadlines on certain weeks are difficult to manage for students. This feeling of accumulation and lack of time to do everything is very much mentioned in the feedback. Late submission of grades is also a source of stress for students. Sometimes, they're uncertain until the end of the semester whether they will pass a course without having to retake it. Another source of stress mentioned is the relationship between students (especially during group work), but also between students and teachers (lack of availability, poor communication, arbitrary group choices). Finally, fear of failure, school fees, and future career choices cause stress.

3.4 Talking about mental health

Whilst approximately 68% of students have experienced ill-being during the academic year.

This ill-being is not necessarily communicated by the respondents. Half of them (48%) feel the need to hide their mental state at school. However, only 18% of them felt that communicating about their mental health had a negative impact on social relations at school. We observe a discrepancy between students' overall opinion on communicating their mental health and their actions.

3.5 Ill-being consequences

We decide to look at whether the ill-being of men and women is expressed in the same way. Respondents who had faced periods of ill-being identified the behaviors in which they recognized themselves. Women seem to be prone to ill-being more than men and to suffer more consequences: we have 5 consequences concerning more than 30% of our women sample against only 3 for our men sample (Fig. 3). Some consequences such as eating disorders affect women more than twice as men, while men seem to be more prone to addictions.

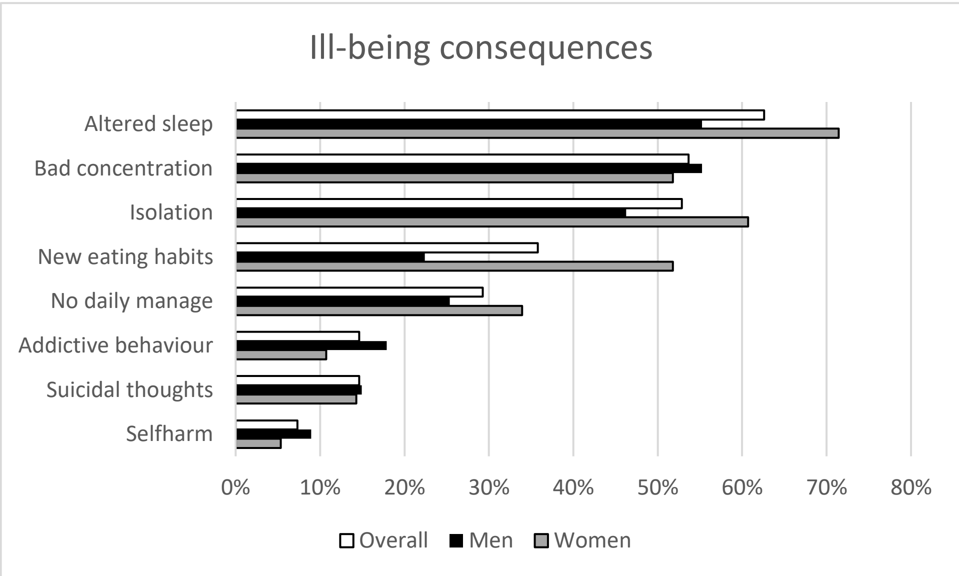

Fig. 3. Consequences of ill-being on men and women

3.6 Improving the consideration of mental health

Students' lack of communication about their mental health can also be explained by their lack of knowledge of the services provided by the school: 64% of respondents felt that they were not aware of the services offered by the school. Depending on the campus, the lack of knowledge goes from 43% to 77%.

More generally, 55% of the respondents did not feel sufficiently informed about the existing programs.

Different activities and support services were suggested to the students. They were asked to identify from a list which ones they could apply for. Students voted for the following solutions (Fig. 4.). As relaxation is the most popular answer, this highlights the importance of reducing the stress felt by student.

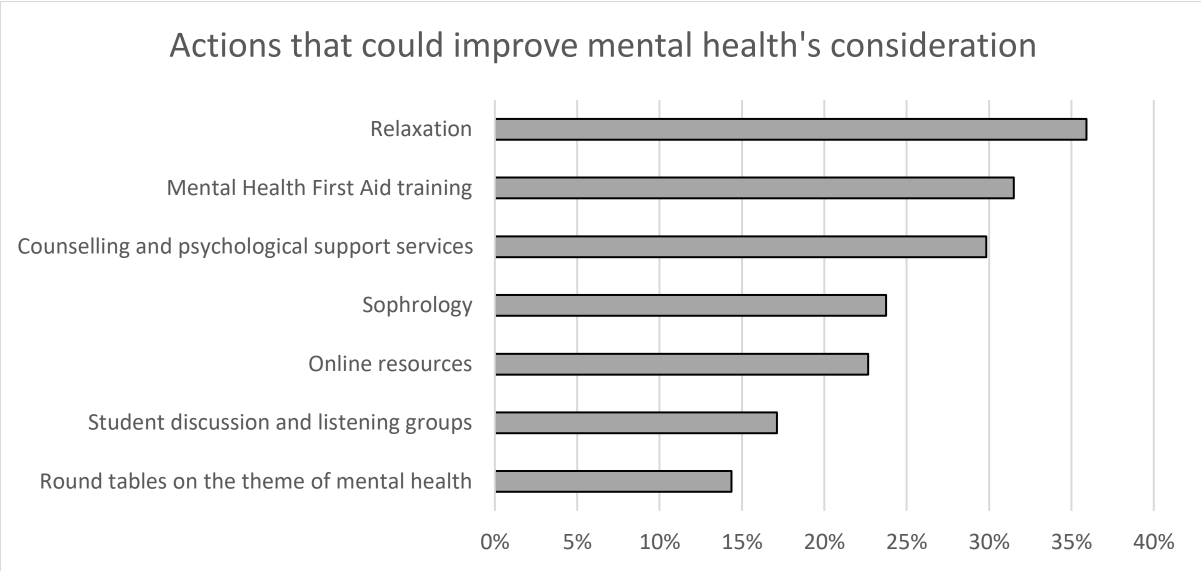

Fig. 4. Solutions to improve mental health's consideration.

Besides these solutions the students asked for more sensibilization actions concerning mental health, to change how the subject is seen by teachers and administration's members. They'd like to have a place, or a school organization dedicated to mental health.

4 SUMMARY AND ACKNOWLEDGMENTS

The survey and this study assessed the mental health of students, identified stressors that the school can act on, and suggested ways to improve the consideration of mental health. Our specific comparisons show that ill-being is present in every study year of an engineering school. Solutions to improve students' mental health must consider the different types of work required of students. Besides, women seem to be particularly affected, it is also to be considered when thinking about solutions.

One of the positive aspects of this work is that it has allowed mental health to be talked about more freely in the school and to show that it is an important issue. It is planned to continue this study next year by collaborating with faculties of psychology and education. It will also be useful to compare and discuss the specific context of engineering student with the work of Jensen (Jensen and Cross 2019), (Jensen et al. 2023). This study indicates that many students perceived high stress and poor mental health to be normal and expected in engineering.

We would like to thank all the students who responded to this survey, as well as all the people who supported this project, including M-P. Cuminal, DEI officer and F. Stephan, campus director.

ABSTRACT

This work describes the use of an arts-based project to stimulate creative thinking about design and sustainability for engineering students of all disciplines and years. ‘Building a Martian House’ was a public art project where a house designed for Mars was built in the centre of the city of Bristol, UK. It was conceived by artists, designed by the public, architects and engineers and built by construction companies. In this work, a workshop for students was developed and run based on this art project. Its aim was to use the challenge of designing for Mars as a provocation to thinking about sustainability in designing for Earth. This workshop was run for two hours for thirty-five students from different years and disciplines and involved two exercises to stimulate creativity. Students completed a pre-and post-workshop questionnaire as feedback. An important part of the workshop was the viewing of an exhibition of sixty images from the Martian house project. These images covered the design, development and building process of the Martian house and artefacts within it. Feedback from the questionnaires indicated that the workshop fulfilled some of the aims, it was interactive and guided, offered teamwork and independent design opportunities and provoked thoughts about resource utilisation and sustainable design.

1 INTRODUCTION

1.1 Background to the project

The ability to think creatively is essential for surviving and adapting to the world's rapid technological, economic, social, and global changes (Beghetto, 2015). Previous work has established the use of arts to increase creativity in engineering courses: "*Bring in the arts and get the creativity for free*" (Csikszentmihalyi, 1996) and an arts-based instructional model for student creativity in engineering suggested: "*exposing engineering students to different ways of thinking is essential for growth in creativity*" (Laduca *et al.*, 2017). Recent literature has covered the types, forms and conditions of learning and characterising knowledge and the artistic experience (Morari, 2023). In other work creativity has been defined as the capacity to create novel ideas, acts, or products that alter existing domains or turn existing domains into novel ones (Styhre and Eriksson, 2008). Asking students to design for a completely novel context and environment could therefore hopefully stimulate their creativity. The aim of this educational project was to use an arts-based project as a springboard to encourage students to gain new perspectives on engineering design for Earth and sustainability. This would be achieved by them participating in a workshop and viewing an exhibition which uses the 'Building a Martian House' arts project (https://buildingamartianhouse.com/) as inspiration.

In August 2022 a Martian House was built as a public art project on the harbourside of the city of Bristol, UK. This explored how a home for life on another planet might be designed. Mars is a place with a harsh environment and limited resources – no air, low pressure, little sunlight, cold and high levels of radiation. It was hoped that designing within these constraints and imagining how a small community would live on Mars would stimulate students to think more about building and living sustainably on Earth. The Martian house started as an idea seven years ago and progressed through workshops, designs, architectural drawings, construction plans, build and opening to the public (see Fig 1 and 2). It was hoped that many of the assets (photos, drawings and artefacts) developed could be shared with students. This would be achieved as part of an installation which would take viewers on a journey through the project asking key questions about reuse of materials along the way. This was a unique opportunity to use this remarkable project as a provocation to learn. Another goal was to bring innovative ways of thinking about sustainability and resource use into the curriculum, as mandated by new UK Engineering Council accreditation guidelines (called 'AHEP4').

This paper covers the background to the work and the Martian House project in section 1, then section 2 outlines the workshop developed for the students, along with both pre- and post-workshop questionnaires put to the students and how the exhibition was developed. Section 3 describes the results of the questionnaires whilst section 4 is a discussion of the work and its limitations. This leads onto some suggestions for further work in section 5, with recommendations in section 6 and conclusions in section 7.

Fig. 2. The Martian House (interior)

2 METHODOLOGY

2.1 Workshop

The workshop was run for undergraduate engineering students from first to fourth year and all engineering disciplines. At the University of Bristol, the disciplines include Mechanical, Civil, Aerospace, Computing, Electronic, Engineering Design and Engineering mathematics. It was advertised through year group lists and through student societies and quickly reached the capped capacity of fifty participants. The authors decided to use a voluntary extra-curricular two hour-long workshop to engage students. This was for several reasons, firstly, it offered a way for the students to engage in creative activities in small groups which would encourage teamwork and facilitated working across disciplines and year groups, secondly it mirrored the process used in the design of the Martian House and, thirdly, it was flexible to the unpredictable numbers. The format of the workshop is illustrated in Table 1:

Table 1. Workshop activity details

Time	Type of Activity	Activity details
2 days before	Student completes	Pre-workshop questionnaire is sent out
20mins	Authors talking to slides	Introduction to Martian Environment, introduction to previous Martian habitat experiments, explanation of design process
15mins	Students creating	Challenge questions: What are the essentials needed to live on Mars? What resources do you think are available on Mars? Make a list.
10mins	Students report back	Joint list of essentials and resources is made
40mins	Students creating	Choose an essential item you'd like to design. Using your list of available resources, explore how you might design your item with what is available. Make a rough design - paper sketch or digital.

10mins	Students report back	Each group presents their design which they have sketched on a large piece of paper
10mins	Authors talking to slides	The artists talk about the design process for the Martian House, its features and ethos.
10mins	Students walking and looking	Students view exhibition as they exit the workshop
Later	Student completes	Post-workshop questionnaire is sent out

This involved a mix of introducing the topic to the students, then allowing them to be creative by working on two lots of challenge questions together. After each of the two lots of working together, they reported back to the whole group. Group size was four to five people in size to promote teamwork and groups were composed of mixed disciplines and year groups. At the end of the workshop, the artists gave a brief description of the design process for the Martian House, its features, including artefacts within the house, but also the ethos of the project.

2.2 Questionnaire

To understand the effectiveness of the workshop, an anonymous pre- and post-workshop questionnaire was devised. The questionnaires received approval from the Faculty Ethics committee before being deployed (Ethics application no.14027). The questionnaires were deployed digitally via link and QR code and sought permission from the participants to be published. These were deployed a few days before the workshop. The post-workshop questionnaire was deployed straight after the workshop.

2.3 Exhibition

Over the seven years that the Martian House project has been in development, there has been a strong focus on visual storytelling. This has included having an artist capture early workshops, the architect creating rendered moving images for a summer open-access activity at the 'We the Curious' science museum and having the final Martian house build and subsequent use captured by a professional photographer and subsequently turned into a short documentary (https://www.youtube.com/watch?v=Migiyq7QxPc). As well as the artists themselves keeping a rich visual record of their work. As a result, it was decided to bring into the workshop a visual narrative element, in the form of a photo exhibition, on the way out of the room where we held the workshop. The reason for doing this, beyond sharing the story with workshop attendees, was to create a visual legacy of the project for other learners to engage with, in line with the 'LEaRN' approach where "all spaces should be considered learning spaces", even, in this case, corridors! (Taylor, 2019)

The exhibition was set up by collating a wide variety of different outputs from the Martian house project and laying them out in a large space chronologically. The artists then selected the most appropriate images, and added five statement-based posters, which captured the essence of the project: “It takes seven months to get to Mars.” “Everything you own will be important.” “You’ll need to fix everything when it breaks.” “Suddenly your rubbish becomes something you might need.” “Can designing for Mars give us the perspective we need for living on Earth?” The students examined the exhibition on the way in and out of the workshop.

3 RESULTS

3.1 Pre workshop questionnaire

Thirty responses out of thirty-five attendees were received to the pre-workshop questionnaire. The first question asked how much the students already knew about three different aspects: design for Mars, design processes and design for sustainability. Figure 3 shows the results for this first question.

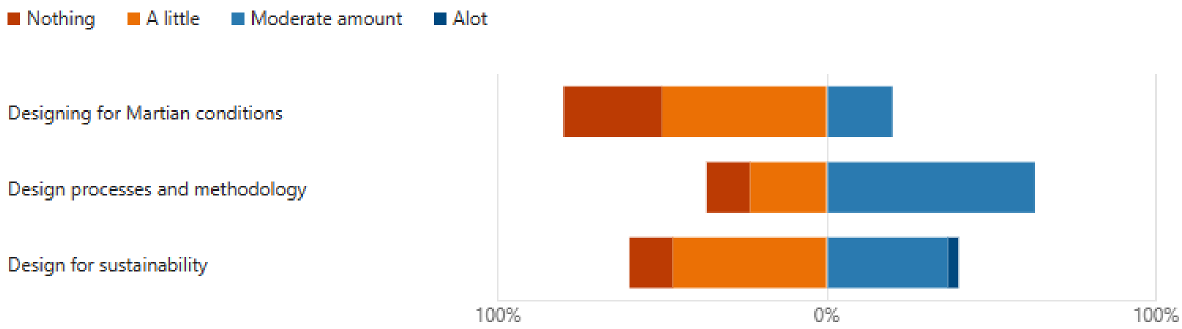

Figure 3: The results of the question: How much do you know about…? (n=30)

This illustrates that the area that the students thought that they were least knowledgeable about was designing for Martian conditions (with 30% knowing nothing and 50% knowing a little). More of them were happy with design processes (with 63% saying that they were moderately confident) but 47% said they knew only a little about design for sustainability.

In reply to the question: what do you hope to get from the workshop? 67% of respondents replied with some variation on ‘Discover more about Mars habitats’, whilst 20% replied with some variation on ‘More knowledge and fun’.

3.2 Post workshop questionnaire

Twenty-six responses (out of thirty-five attendees) were received in response to the post-workshop questionnaire.

In response to the question ‘has the workshop changed how you might think about designing for Earth?’, all participants answered either Yes (50%) or Maybe (50%). When asked to explain this answer, 70% of the response were variations on “*we need to use the resources available to us more deliberately*”, and “*the focus on designing with limited resources could be easily applicable to Earth*”. In contrast, one student pointed out *"I don't think there'll be acceptance on Earth for the basic living style on Mars*" and another very practically said: "*It personally has made me want to design a hydro/aeroponic system to use at home…*".

In response to the question 'How much more do you know about…", 92% of students felt that they had learned at least a bit more about designing for Martian conditions, 85% said that they had learned at least a bit more about design for sustainability, then 81% said that they had learned at least a bit more about design processes.

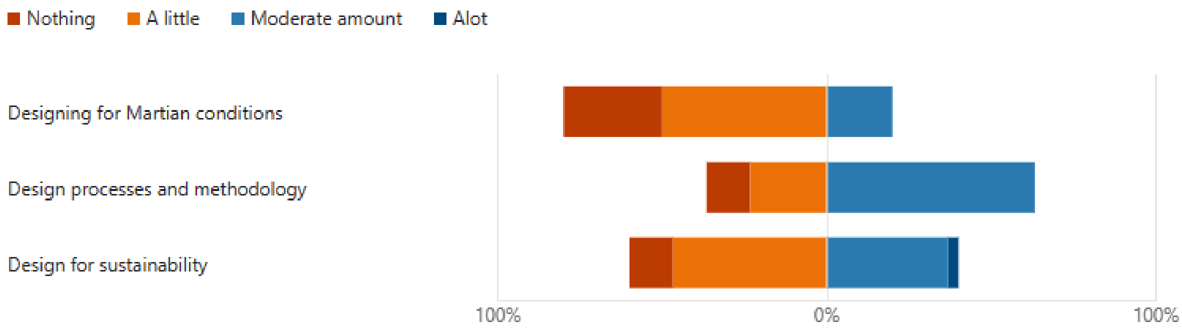

Figure 4: Responses to the question: 'How much more do you know about…" (n=26)

In response to the question 'What did you enjoy about the workshop?', students mentioned "*Good mix of independent work and being told stuff*", but also "*the freedom to think creatively*" and "*the atmosphere was great*". Several students also mentioned "*working in teams*".

In response to the question 'What would you change about the workshop?', students suggested "*maybe snacks*" (!), 20% said "*make it more technical*", 20% said "*more guidance on the design*" and 12% said "*more on sustainability*". In response to 'any more comments?' there were few responses mostly expressing thanks. There was one comment on the exhibition: '*Interesting exhibition*'.

4 DISCUSSION

This work has used an arts-based project as a provocation to creativity in design and thinking about sustainability. There were many limitations to this research. Only one two-hour-long workshop with thirty-five students has been run up until now, so the results are necessarily preliminary. It is challenging to measure how successful this was from questionnaires with just a few questions, the number of students responding were thirty and twenty-six for the pre- and post-workshop questionnaires, which mean that the sample size was small. As the responses to the two questionnaires were anonymous, it was not possible to know if the same people answered both the questionnaires, so it was hard to compare the answers. However, it appeared from the data so far, that the workshop did encourage the students to change how they might think about designing for Earth and that most of them learned at least a bit more about designing for Martian conditions, the design process and design for sustainability. Interestingly, and perhaps not surprisingly, their response to ‘how much more do you know about…?’ was a mirror image of their response to ‘how much do you know about…?’. It is debatable whether people are a good judge generally of what they think that they have learned. In addition, whether what students **think** they want to learn is not necessarily the same as what they **will** learn.

With a short exercise such as this, it was not surprising that the students requested more technical information and more guidance. Indeed, the request for more technical information indicates that they are emphasising technical aspects instead of staying in the creative space. More information could be made available, but there is also never enough information! As authors, we wonder if we should push in the opposite direction, to encourage more integration of the arts/social aspect. We could encourage the students to go beyond their technical training: how does an artist approach? Some of the questions in the original Martian House project included: “Can designing for Mars give us the perspective we need for living on Earth?” and “How can we live well on Mars?” From the feedback it appeared that the format of the workshop with a mix of disciplines and years worked well for the students.

5 FURTHER WORK

Eventually it is intended to turn the workshop into a session within the first year Engineering Design unit which is taken by six hundred students across the faculty. One of the learning outcomes for this design unit is to help students see the interrelationship between society and engineering and to encourage thinking about sustainability. Ideally, the workshop would encourage students to critically examine their assumptions, values, and biases and reflect on how these factors influence their engineering practice. Whilst we have attempted to measure the impact from a short workshop on the participants, it would also be interesting to explore our own journey, having been active participants in the artwork.

6 RECOMMENDATIONS

The authors’ thoughts on recommendations from this work are as follows:

1. Arts-based projects can stimulate creativity in engineering and lead to a surprising amount of learning.
2. Unexpected contexts can offer new perspectives on challenging problems.
3. Mixing the students in terms of disciplines and years worked well and led to a good atmosphere.
4. Students will tend to ask for more and more technical information but can be encouraged to stay in ‘uncertainty’ and the creative space.
5. Workshops should include explicit opportunities for student reflection, self-assessment, and self-awareness. Reflection prompts, journals, and group discussions may be used to facilitate this process.
6. When exploring an education project, it is interesting for the practitioner to ask how being involved may impact on their own work, thoughts and biases.

7. Artefacts made during an arts-based project can add to an engineering education context.

7 CONCLUSIONS

This paper describes the use of an arts-based project to build a Martian House to stimulate creativity for engineering students in thinking about designing for Earth. A workshop for students was developed and run with the aim of using the challenge of designing for Mars as a provocation to thinking about sustainability in designing for Earth. Thirty-five students attended the workshop and feedback was collected. An exhibition showing images of the design process for the Martian house was set up along the corridor to the venue and formed part of the workshop. The feedback indicated that whilst the format of the workshop worked well and almost all the students felt that they had learned at least a bit more about the areas covered, a percentage of the students wanted more technical information and guidance. Further work will involve incorporating the workshop into an Engineering design unit in the common first year of Mechanical, Civil and Aerospace Engineering degrees.

8 ACKNOWLEDGMENTS

This educational research project has been funded by the Faculty of Engineering at the University of Bristol. The Martian House was created by artists Ella Good and Nicki Kent, in collaboration with Hugh Broughton Architects and Pearce+. It was presented in partnership with Bristol's M Shed and funded by The Edward Marshall Trust.

ABSTRACT

At the Norwegian University of Science and Technology, a new cross-campus statistics course for approximately 1000 engineering students was planned for the fall of 2020. Due to the pandemic, digital learning resources were developed to allow students to work from home or campus, individually or collaboratively. These resources include short learning videos, automatically graded exercise sets, and Jupyter Notebooks for Python coding. Since 2020, digital learning resources have been essential for teaching statistics to engineering students across three campuses, and remotely. To help students navigate digital resources, on-campus activities, and assessments, each week of the semester was structured according to specific learning paths. However, asking the students to watch videos and work on exercises before on-campus or digital lectures is no guarantee that they will do so. For this study, we use video and assessment statistics, along with survey results, to determine to what extent the proposed learning paths were followed and the

[1] *Corresponding Author*
T. Bjørnland
thea.bjornland@ntnu.no

perceived usefulness of the various elements that make up a learning path. In surveys, the engineering students at the Norwegian University of Science and Technology report great satisfaction with videos and digital assignments (along with scaffolding exercises) in the statistics course. By utilising digital user statistics, we observe patterns of engagement with digital resources that are closely tied to the proposed learning paths.

1 INTRODUCTION

1.1 Background: A new statistics course in the middle of a pandemic

In 2016, the Norwegian University of Science and Technology (NTNU) merged with three Norwegian colleges. Therefore, NTNU now offers bachelor engineering programs in three different counties, with many basic courses running in parallel across three campuses. The statistics group at the Department of Mathematical Sciences has since 2020 been offering the mandatory third semester undergraduate statistics course (7.5 ECTs). This course covers well-known topics such as probability and probability distributions, reliability, descriptive statistics, and basic statistical inference. In addition, the students complete one module relevant for engineering applications; design of experiments and statistical process control; measurement error and error propagation; or data science and statistical learning. Approximately 1000 engineering students from 12 different study programs enrol in this course annually (some programs also offering remote studies).

In the fall of 2020, a new team of lectures located across the three campuses were to develop and teach this cross-campus statistics course for engineers for the first time. Due to the ongoing pandemic and social restrictions, we had to plan for a completely digital off-campus learning environment. Geographical and multicampus challenges then being erased, the team decided to avoid giving parallel digital 'local' lectures. Instead, we could take on different development tasks; developing short learning videos (5-15 min) as a way of introducing new material to the students; giving a complementary digital session with worked examples; developing weekly digital quizzes; and preparing material for the various project modules. Despite a challenging and hectic semester, we were left with the overall impression that we had developed a resource bank and a way of coordinating teaching that could benefit both the students and us. Since then, we have built a blended learning environment for hybrid cross-campus (and remote) teaching. We *intend* our students to watch learning videos at the beginning of the week (especially before they attend the mid-week campus-based lectures), and we *suggest* that they start working on the weekly assignments early so that they manage to finish in time for the Friday evening deadline. Now we ask ourselves, are our students actively engaged?

1.2 Motivation: Blended learning

The motivation behind this paper is twofold. First, we present a post-covid blended learning environment in statistics for engineering students. As a definition of blended learning, we adopt the following definition of Boelens et al. (2015): "…*learning that* *happens in an instructional context which is characterized by a deliberate combination of online and classroom-based interventions to instigate and support learning*”. A shift from mainly classroom-based instruction to digital resources can foster students’ control of their own education in terms of mode and pace of learning (Castro 2019). Furthermore, differentiated modes of instruction and learning materials can be valuable for heterogeneous student groups (Boelens et al. 2018), also in terms of living circumstances (Guppy 2021). In an engineering mathematics course, Liestøl (2020) found that students often waited until the last day before assignments to watch videos and skipping videos considered less important or too lengthy. As students may show up unprepared for in-class sessions if the required pre-class workload is too high the length of learning videos is typically recommended to be 6-9 minutes (Guo et al. 2014) or 12-20 minutes (Lagerstrom et al. 2015). For this study, we will compare data from the two ‘post-covid’ semesters fall 2021 and fall 2022, focusing on the engagement (both overall use and time of use) with learning videos and digital assignments. Our aim is to gain insight into students’ engagement with digital resources.

2 THE COURSE

2.1 Course content and structure

This paper concerns students’ engagement with digital learning resources during the first nine weeks of the statistics course for engineers at NTNU. This part of the course is assessed with an individual digital exam that counts towards 70% of the final grade (the remaining 30% of the grade is based on a group project in one of three optional modules). Each week is defined by a specific topic: 1. Descriptive statistics; 2. Probability of events; 3. Stochastic variables; 4. The binomial distribution; 5. Poisson processes and reliability; 6. The normal distribution; 7. Estimation and confidence intervals; 8. Hypothesis testing; 9. Simple linear regression. For each topic (and therefore each week) we have developed 3-4 short learning videos; a catalogue of in-depth examples for campus-based sessions; Jupyter Notebooks with worked data examples in Python; and digital assignments. The students are required to pass (i.e., at least 8 out of 10 points) at least 6 of these weekly assignments, while all other activities during these first nine weeks are voluntary. We offer both on-line and on-campus tutoring each week. The digital exam questions are of a similar type as the quizzes, but without access to other tools than calculators and formula sheets.

2.2 Weekly learning paths

For each topic (and week) we present the students with a recommended learning path, see Figure 1 for a generic representation. We recommend that the students watch the learning videos and attend the 45 min digital cross-campus plenary overview lecture in the beginning of the week, and especially before attending the mid-week campus lecture. The campus lecturer organises this session based on the assumption that the students have watched the videos. The deadline for the weekly assignments is at the end of the week, but we recommend that the students start out early (the first few exercises are always at an introductory ‘get-started’ level). All materials and information necessary to complete a topic become available to our students in our ELS (Blackboard) on the Friday prior to week in question.

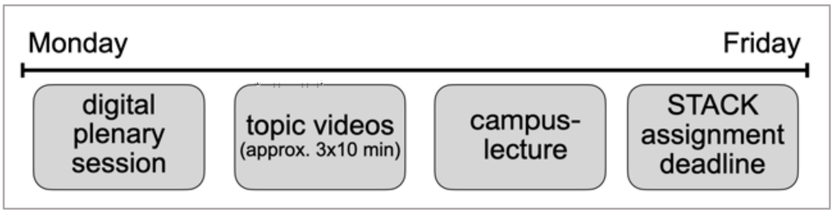

Figure 1. Weekly learning path

2.3 Learning videos, Jupyter Notebooks and assignments in STACK

Our learning videos are hosted in Panopto, one folder for each week, three or four videos per topic. The videos are based on animated Keynote presentations where the lecturer introduces the main concepts of the topic. The length of each video is between 5 and 15 minutes. Python is the preferred programming language for the engineering programs at NTNU, and therefore also used for data analysis and computations in the statistics course. Any data analysis presented in a video may be reproduced by our students by interacting with the corresponding Jupyter Notebook. Notebooks for generic calculations with probability distributions are also available to them. Each week, the students are also given a digital assignment created with the STACK question type in Moodle. For each question, all students get a similar statistical problem to solve, but the numbers (and therefore also the answers) are random and individual. We encourage collaboration on methods, but each student must submit his or her individual calculation. We have also developed corresponding step-by-step scaffolding exercises in STACK so that the students may check intermediate calculations and get tips on how to proceed. Some of the weekly exercises guide the students to a Jupyter Notebook where they must edit and run code and report an output back into the STACK-assignment.

2.4 A (subtle) change between two semesters

For historical reasons, we started teaching this course with a one-week delayed deadline for assignments. The learning path presented in Figure 1 was promoted by lecturers in 2021, but the actual assignment deadline was in fact one week later. During that semester, local lecturers observed that students tended to be behind with their work, so that the weekly campus lecture made no sense to them. For 2022 it was therefore decided to give the students a much tighter deadline (see Figure 1).

3 METHODOLOGY

For this study, we use anonymous video and assignment statistics to determine to what extent the proposed learning paths were followed in 2021 and 2022. We also present anonymous survey results regarding the perceived usefulness of the various elements that make up a learning path. Video statistics were downloaded from the platform Panopto where the videos are hosted. We used the count of all viewings of length greater than four minutes as an estimate of the number of students watching a certain video. Averages were taken over the number of videos for each week (3 or 4). The exam period was not considered. For the assignments in STACK we report the weekly number of attempts as well as the start day of these attempts. In both 2021 and 2022 an anonymous survey was sent to all students, the response rate being approximately 22% in 2021 and 32% in 2022. In both surveys, students' perceived learning outcomes from various learning resources were reported. The results of the data analysis are presented in Section 4, while a discussion of our findings is given in Section 5. Data visualisation was performed using ggridges (Wilke, 2022) for ggplot2 (Wickham, 2016) in R (R Core Team, 2022).

4 RESULTS

4.1 Assignments in STACK

In Table 1 we present the number of attempts for the weekly assignments. The number of attempts for the first assignment is taken as an estimate of the number of students following the course. In both 2021 and 2022, the number of attempts was above 90% throughout the first six weeks, before it dropped to nearly 60% for the ninth topic. The required test score was 8 out of 10, and in terms of average scores we observe a decline towards last weeks, but no notable differences between the two years.

Table 1. The number of attempts per exercise set (assignment) in STACK (exam period excluded) as well as the average total score (out of maximum 10) and corresponding standard deviation (SD). Percentages are based on the number of views relative to the estimated number of active students (1147 in 2021, 1076 in 2022).

Topic	1	2	3	4	5	6	7	8	9
2021	1147 (100%)	1106 (96%)	1094 (95%)	1098 (96%)	1102 (96%)	1077 (94%)	975 (83%)	863 (75%)	704 (61%)
Score (SD)	8.9 (1.9)	8.9 (1.7)	8.7 (1.7)	8.9 (2.0)	8.5 (2.2)	8.2 (2.1)	7.9 (2.8)	7.5 (3.4)	7.4 (3.4)
2022	1076 (100%)	1056 (98%)	1044 (97%)	1037 (96%)	1022 (95%)	999 (93%)	931 (87%)	798 (74%)	677 (63%)
Score (SD)	9.0 (1.4)	8.6 (2.0)	8.6 (1.7)	8.8 (2.1)	8.6 (1.9)	8.3 (1.8)	7.9 (2.7)	7.2 (3.3)	7.6 (3.1)

In Figure 2 we present frequencies of starting dates for the weekly assignments. Here, we observe a substantial difference in student behaviour between the two semesters. In 2022 most students started the assignment on Mondays. In 2021 however, we observe two 'modes' of student behaviour. Approximately half (or even less) of the students started working on the assignments in the intended week (uniformly spread out between Monday and Friday), while the other half postponed the exercise set until the following week, i.e., the week of the deadline.

In 2022 there are two additional observations to be made. Prior to week 7 and 8, some students reached out to us regarding taking an autumn break (in line with the

Norwegian school holidays) and requested learning materials to be published one week prior to the schedule. The work of these students can be seen as an early peak in weeks 7 and 8. Furthermore, because some students have side-jobs during the week, they requested the deadline to be moved from Friday to Sunday so that they could use Sundays to catch up on their studies. This delay can be seen in Figure 2 (2022) for weeks 8 and 9.

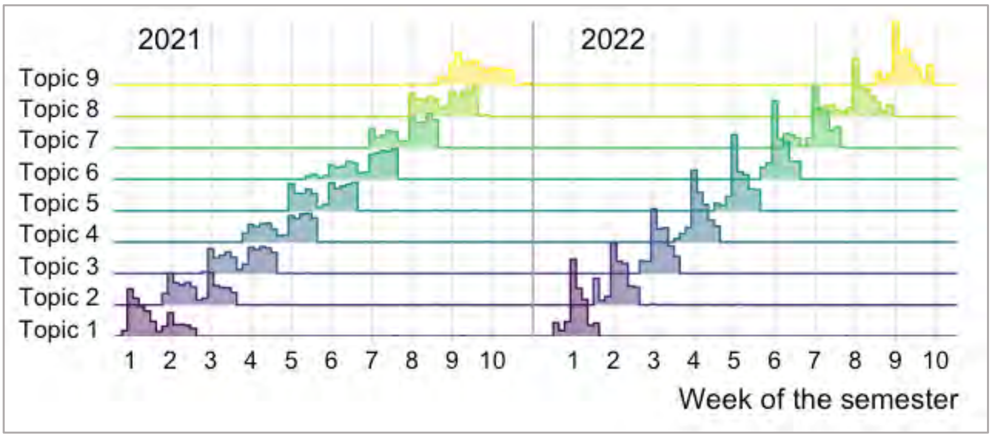

Figure 2. Frequencies of starting dates for weekly STACK assignments in 2021 and 2022, comparing starting dates per topic between the two semesters. Monday is the first day of each week (grey vertical lines). In 2021, exercises were made available the Friday before the topic was covered and the deadline was Friday two weeks later. In 2022, exercises were similarly made available the Friday before and the deadline was Friday one week later.

4.2 Learning videos

Video view counts per topic (1-9) are presented in Table 2. By assuming that few students watched substantial proportions of each video more than once (not counting the exam period) and that few students watched videos in groups, these numbers can be taken as estimates of the number of students engaging with this digital resource. We observe that between 70% and 80% of students watched learning videos each week, but with a drop in view counts towards the end which follows the same trend as for the assignments (Table 1).

Table 2. The average number of views (at least 4 minutes) per video for each topic in the fall semesters of 2021 and 2022 (exam period excluded). Percentages are based on the number of views relative to the estimated number of active students (1147 in 2021, 1076 in 2022).

Topic	1	2	3	4	5	6	7	8	9
2021	1043 (91%)	978 (85%)	1015 (89%)	860 (75%)	827 (72%)	884 (77%)	782 (68%)	901 (79%)	788 (69%)
2022	813 (76%)	917 (85%)	843 (78%)	841 (78%)	780 (73%)	797 (74%)	750 (70%)	796 (74%)	557 (52%)

In Figure 3 we present frequencies of video viewings for the nine topics, comparing each topic between the semesters of 2021 and 2022. We see a trend that is very similar to that of the assignments (Figure 2). In 2022 most students watched videos on Mondays (thereafter Tuesday and Wednesday), while in 2021 we again observe two 'modes' of student behaviour; approximately half of the students followed the intended schedule, while the other half was delayed by one week.

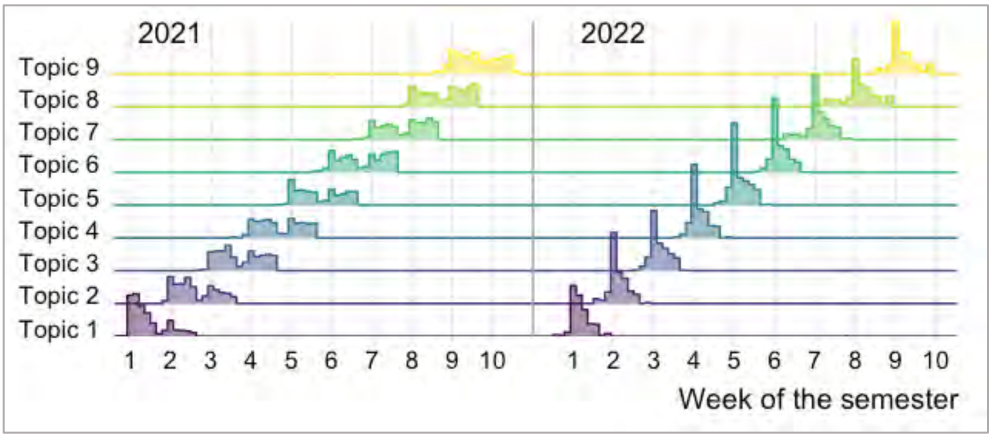

Figure 3. Frequencies of video viewings in 2021 and 2022, comparing dates per topic between the two semesters. Monday is the first day of each week (grey vertical lines).

4.3 Survey results

In 2021, students were asked to select the top four (out of thirteen) learning resources for their (perceived) learning outcome. Out of 251 respondents, 89.2% selected the STACK assignments, 74.1% selected the learning videos, 54.2% selected previous exam questions, and 52.2% selected the STACK step-by-step scaffolding exercises. Only 8% of respondents rated the Jupyter Notebooks top four. The digital plenary lectures, campus lectures and textbook were selected among top four resources by 14.3%, 12.7% and 14.3% of respondents, respectively.

In 2022, students were asked to evaluate their perceived learning outcome of each resource individually. For the digital STACK assignments, 82.3% of respondents reported a good or very good learning outcome and for the learning videos, 76.2% of respondents reported a good or very good learning outcome. The corresponding results were 76.5% for digital scaffolding exercises, 42.4% for previous exam questions, 35.5% for Jupyter Notebooks, 33.8% for the digital plenary lecture, 48.0% for the campus lecture, and 28.1% for the textbook.

5 DISCUSSION

In this paper we have presented a method of blended teaching in a statistics course for engineers. In this course we propose a learning path that students may use to navigate various digital recourses and on-campus activities. The deadlines for the mandatory element of the course (weekly quizzes) are set by us, and as seen in this paper the deadline has a clear impact on the overall pace of studies. However, by using short topic videos as the main 'lecturing' format, we have shifted the control of timing and pace of lectures from the lecturer to the student.

When we in 2021 gave the students a late deadline (one week after the topic was 'lectured'), about half of the students were delayed both when it came to starting the assignments and watching the videos. As the videos were intended to be viewed prior to the mid-week campus-lecture, the delayed students were likely either skipping all lectures or having a poor learning outcome if attending. This delay in student behaviour also led one of the campus-lecturers to change the format of the session; instead of covering examples that should expand the week's curriculum, the lecturer had to introduce the curriculum. Based on statistics from 2022, we see that a stricter deadline for the assignments coincides with the students engaging with the digital resources in line with the suggested learning paths. The proportion of students doing the assignments and using the short topic videos as a learning resource was however similar between these two years.

Although we have no official statistics, we would guess that by the end of the first nine weeks, about 30% of the students attended digital and campus-based sessions. Clearly, far more students watched videos than attended lectures and one can of course speculate whether attendance would improve if less material was covered by the videos. From survey results we also see that the students rate the videos as far more important for learning than the lectures. This is somewhat unsurprising given the attendance rates, and when keeping in mind that the videos introduce new theory which the campus sessions build upon and extends.

Our results must also be viewed in the relevant context; both due to the pandemic and the cross-campus nature of the engineering programs at NTNU, our students are used to – and expect – a digital or hybrid learning environment in basic courses. For us, the use of learning videos instead of solely campus-based lectures ensures fairness and equal opportunities across campuses. It should be noted that the efforts made by the team of lecturers to produce all learning materials in 2020 (and thereafter improving and updating) have been substantial. However, we have tried to make a course where we minimize the amount of work being done in parallel across campuses and distributed various development tasks among the team of lecturers.

In this study we have focused on students' use of digital learning resources, revealing different strategies chosen among students in two semesters with the same blended learning environment. We find that with sufficient guidance - which includes both learning paths *and* appropriate deadlines - to the navigation of learning resources, the engineering students successfully engage with digital learning resources for learning statistics. Of note, our top-rated learning resources were developed according to current advice; short learning videos (5-15 min) and exercises with immediate feedback (formative assessment) complemented by step-by-step help exercises (scaffolding). For further work, we are focusing on improving the integration of Python programming, and on the end-of-term team-based engineering projects.

ABSTRACT

The pandemic has accelerated the trend towards online and hybrid learning with many educational institutes pivoting their education to online learning environments and has subsequently transformed societal expectations. There have been many benefits associated with these changes (e.g., multi-dimensional interactions, flexibility and deep learning). As we move into more online education due to changing needs and demands from students, how best to adapt our education for multi-modal learning environments can be a challenge. Getting our education ready for a multi-modal age is bringing about disruptive changes forcing us to rethink what we teach and how we teach it. **Thus, the objective of this paper is to present a framework that will allow for the evaluation of curriculums and enable educators to create sustainable, flexible educational environments relevant for multi-modal learning environments while remaining at the forefront of educational needs.** In this paper, we present the 5-phase approach that we used to assess our programme and redesign our curriculum. The five phases include: Inventory, Analysis, Evaluation, Design and Implementation. We will present the highlights from our experience and the challenges we have had to overcome. The framework that we present is applicable to different computer science, spatial and data engineering programmes that require a mix of theoretical and hands-on practicals.

---

1 INTRODUCTION

1.1 Background

The pandemic forced educational institutes to pivot their education to online learning environments and has subsequently transformed societal expectations. With the advancement of digital technologies, we can provide very rich and multi-dimensional learning environments. Although there have been many benefits associated with these changes (e.g., multi-dimensional interactions, flexibility and deep learning) there are still many challenges that can result in poor and often inadequate educational experiences. Since staff have had to convert their courses to make them fit for online delivery, which served an immediate purpose, there now has been time to reflect and see room for improvement.

At the same time that educational transformations are taking place, so too are transformations within our own discipline of geospatial information and earth observation sciences due to advances in technologies and the integration of machine learning and artificial intelligence methods. A key part of the skills students require are those of data, software and spatial engineers that range from the creation and fusing of data to make data useable and operational or software and technological engineering. These advancements highlight the need for us to update our curriculum so that we can incorporate new skills, methods, technologies, knowledge and competences as they relate to the geospatial field and the needs for this profession while also transforming how we teach. As we move into more online education, due to changing needs and demands from students, the question now is how best to adapt our education for multi-modal learning environments and create a high-performing digital education ecosystem that is flexible. **Thus, the objective of this paper is to present a framework that will allow for the evaluation of curriculums and enable educators to create sustainable, flexible educational environments relevant for multi-modal learning environments while remaining at the forefront of educational needs.**

1.2 Online education

In 2020, all face-to-face (f2f) education around the world closed. The ad-hoc necessity to provide online education affected all aspects of education (Blanford et al. 2021) that required transitioning learning environments in a short-period of time (Bryson and Andres 2020). Staff were required to transform, adapt and develop infrastructure, curriculum, pedagogy and skills (e.g. digitalization of education and incorporation of video, videoconferencing and other media (Smolle et al. 2021)) to make courses ready (e.g. (Bogdandy, Tamas, and Toth 2020)) instantly. Many challenges were faced that included barriers due to technology, internet connectivity and availability (Demuyakor 2020, USAID 2020, Cullinan et al. 2021), ethical concerns (see references within (Turnbull, Chugh, and Luck 2021)) related to privacy (Rajab and Soheib 2021), inclusion (Parmigiani et al. 2021) and inequality (Pittman et al. 2021). Although the transition to online education started as a response to the pandemic, finding the balance between f2f and online learning is the next step in developing resilient educational systems (e.g. (Schultz and DeMers 2020)).

Many master's degree programmes are available in a variety of formats (full-time, part-time, face-to-face, blended, online). Online is increasing in popularity with working professionals who are unable to move to the education facility full-time due to family obligations and are in a good job. Flexible study options via part-time and online provides many professionals the opportunity to continue to advance their existing competences and develop new skills and knowledge. Different modes of education can include **blended learning/flipped classroom** (combines face-to-face classroom time with online learning) or b**lock mode learning** which involves intense face-to-face study over a fixed period, often weekends or consecutive days allowing students to book time off work in advance. In this paper we focus on education in fields that merit from the benefits of online education but are also greatly dependent on hands-on learning by doing such as lab-work and field experiments, often requiring physical presence of students. For education in these fields, we need to find an optimal mix of multiple education modes.

1.3 Geospatial Engineers and Spatial Data Engineers

Geospatial engineers and Spatial Data engineers require a variety of competencies that include a range of workplace, academic and personal skills alongside a range of technical skills (see (Blanford et al. 2020) for competencies). In essence the types of skills needed by geospatial professionals include:

- Data engineering
- Data Visualisation and Exploration
- Spatial Analysis
- Modelling and scripting that may extend to software engineering with the creation of new technologies and applications.
- Machine Learning & Artificial Intelligence
- Big Data Analytics
- Open Science, Ethics & Governance

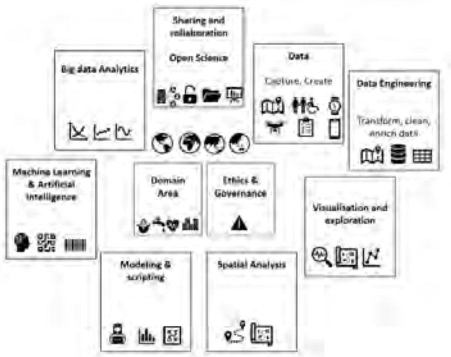

Fig 1: *Overview of the skills needed by geospatial professionals.*

With technological improvements, dealing with increasing amounts of data in different velocities, volumes and validity (V's), big data analytics and processing is of increasing importance alongside the need for using different types of information across a variety of domains such as responsible GeoAI, Disaster Resilience, Resource Security and GeoHealth. Students need to learn these skills to enhance decision making, develop solutions and for achieving the many sustainable development goals across a variety of disciplines.

The master's programme that we offer, enables graduates to address worldwide challenges in a local context using the core knowledge areas of Geo-Information Science and Earth Observation. The programme aims at providing graduates with the skills and knowledge that enable them to provide solutions that contribute to the sustainable development of societies. We have created an international multi-cultural educational environment that brings together students and staff from around the world. Through this diverse learning environment, we provide a rich learning experience that enables for the co-creation of geospatial solutions for addressing global challenges and provide solutions for sustainable development.

2 METHODOLOGY

2.1 Framework for redesigning the curriculum.

Redesigning of curriculums or educational programmes requires many aspects of the programme to be (re)considered, which all start with creating and updating measurable learning outcomes, selecting appropriate and effective teaching strategies to enhance learning experiences and aligning assessment methods with learning outcomes.

In general, redesigning of curriculums is a multi-staged process that involves (i) *analyzing* the current educational situation by gathering information, (ii) *designing* a new curriculum, (iii) *implementing* of updates and changes, and (iv) *evaluation* of the updates (Nomme and Birol 2014). We have adapted these stages to fit our needs and created a 5-phase approach (Figure 2). The information gathered during Phases 1-3 will serve as input to Phase 4, designing the curriculum. Once the design phase is completed and the courses updated, we can enter Phase 5, the implementation phase. For this study we will mainly report on Phase 1-3.

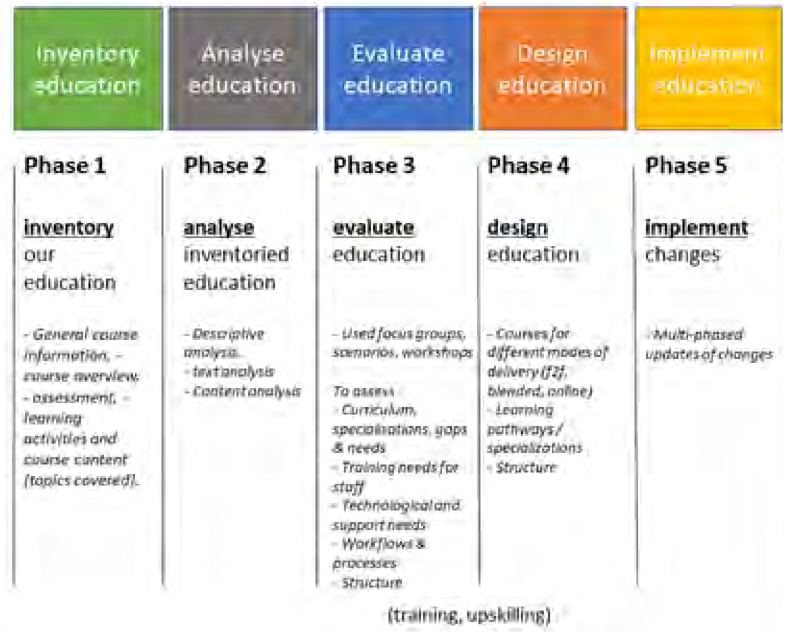

Fig 2: *Overview of the 5-phased approach for innovating the curriculum in a degree programme.*

Each of the five phases are described briefly below:

- **Phase 1: Inventory** our education captures different elements associated with teaching and learning (content, assessment, community). These include general course information, course learning outcomes, how students are assessed and what learning activities are used, what topics are covered. Pedagogical information for each course was obtained from course coordinators. Each course coordinator was provided with a form for their course pre-populated with existing information from the study guide. All coordinators checked the information and provided missing or incomplete information on learning activities, learning outcomes and information on content.

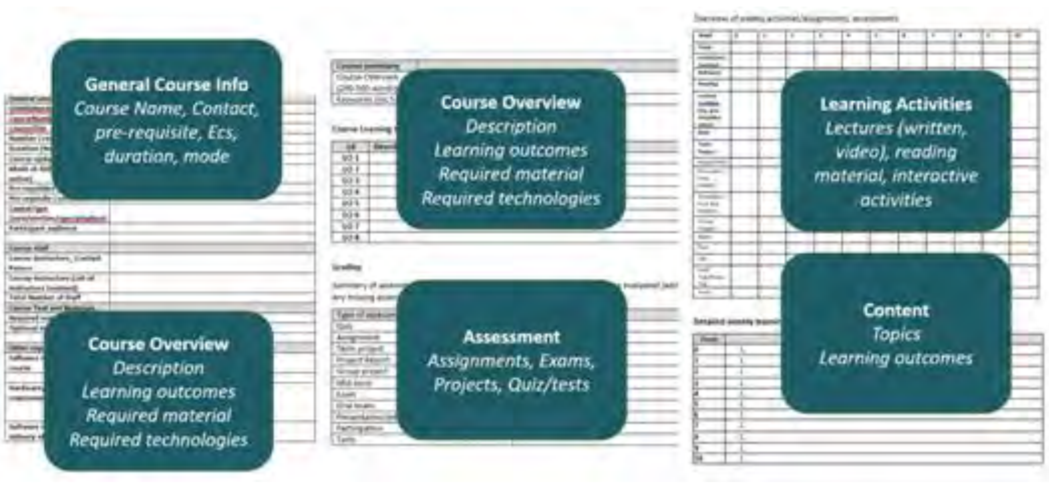

Fig 3: *Example of a form used to capture detailed course information. The elements were transferred to an excel spreadsheet and later used to populate a database.*

- **Phase 2: Analyze** the data captured in the inventory (what didactic methods were being used; what assessments were used; what topics were being taught). The inventoried information was analyzed using descriptive statistics. Voyant Tools (https://voyant-tools.org/) was used to analyze text and included creating word clouds. Thus, we examined the curriculum, relationships between courses, identified gaps or isolated topics (Fig 4) and evaluated the programme and how what we offer relates to the geospatial competencies required in this field.

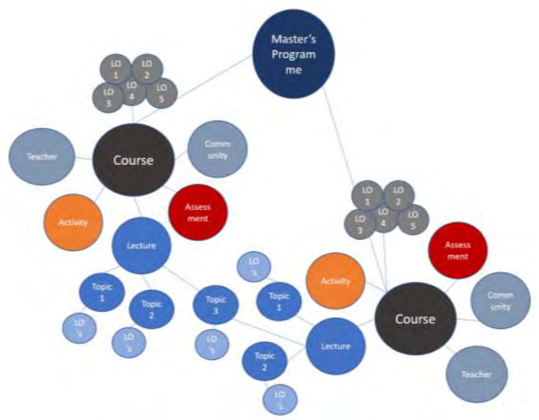

Fig 4: Conceptualisation of course components for the master's programme and how courses may be connected.

- **Phase 3**: **Evaluate** our education. We further evaluated our education using findings from Phase 1 and 2, combined with external inputs from, for instance, our professional advisory board. These served as input to discussions and activities during workshops, interactive focus groups and collaborative design sessions. Internal and external surveys were used for additional data gathering and polls to finalize decisions and clarify ambiguities during sessions. We included students and staff during workshops and discussions. The findings from Phase 1-3 will serve as input for developing training and designing the programme.

- **Phase 4**: **Design** education for multi-modal learning environments. During this phase we will conceptualize the curriculum and assemble the pieces using the information collected during Phase 1-3. To aid in designing the programme we have developed a set of small pilots that will allow us to test new approaches, workflows and processes so that we can assess the feasibility of incorporating these changes and identify challenges. The pilots include:
    - (i) *appreciation for online teaching:* develop workshops and training to promote digital education skills and enable staff to develop skills for designing courses for online delivery.
    - (ii) *assessments*: evaluate variety of testing types to achieve more efficient and effective testing.
    - (iii) *designing courses and a curriculum* that use different didactical methods with the aim of achieving the same or higher learning results.
    - (iv) *create new learning pathways/specialisations*: design a new learning pathway for online delivery.

  For the design of courses and curriculum we will incorporate design elements and use storyboarding to aid in visualizing a course and the elements that make up a course (lecture, learning activity, assessment, interaction) (Laurillard 2021) to help us visualize what we are teaching and how. We will also apply these when designing learning pathways / specialisations to gain an overview of our programme and check how they contribute to the overall programme learning outcomes. We will create scenarios to examine changes in structures and how they impact different modes of learning and course flows - how courses fit together and how sequence of courses translate between different modes (face-to-face <- – -> online).

- **Phase 5: Implementation** of new courses and curricula. Changes and updates will be phased in. In particular for a multi-year master's programme, this phase can be more challenging. One-year master's programme can be changed with little consequences for new or previous cohorts of students. Multi-year programmes need to plan for curriculum changes well in advance in order to anticipate effects on students that will start or finish up to at least three years from 'now'.

3 RESULTS

We assessed all courses in our programme (N=68). The mode in which courses were delivered are predominantly face-to-face, with some online (N=3) and hybrid (N=5). On average, courses ran for 10 weeks with some running for 5 or up to 12 weeks. A variety of software is used that ranges from open source to proprietary software (Figure 5). A summary of the findings from the inventoried courses are captured in Table 1.

Fig 5: Word cloud of software utilized during the programme.

Table 1: Summary of findings from inventory

Topic	Findings	Adjustments and improvements needed
general course information	- Most details were provided - Course names not very informative - Mode of delivery is predominantly f2f - Duration of courses predominantly 10 weeks - Course levels (introductory, advanced) are not clearly defined.	- Course names could be improved - Ability to deliver in multiple modes (face-to-face, hybrid, blended, online) needs to be addressed.
overview of courses	- Course descriptions varied in detail - Learning outcomes provided for courses - Pre-requisites not defined for all courses	- Course descriptions need to be standardized. Information needs to be more concise and informative. - Learning outcomes for courses need to be refined.
assessment: how students were evaluated	- Variety of assessments are used. - Terminology of assessments varied. - Assessments were predominantly based on assignments, group projects and tests.	- Standardization of definition and naming of assessments. - Balance type of assessments - Balance individual and group-based assessments
learning activities	- Emphasis is on contact hours - Learning activities consist predominantly of lectures and supervised practical's/tutorials	- Need to balance the use of different learning activities/types to encourage more active learning. - storyboard courses and view breakdown of types of learning activities used (acquisition, discussion, investigation, collaboration, practice, production and assessment) (Laurillard 2002, Laurillard 2021) to enhance learning activities.
details about the content	Mixed level of details	Additional details are needed, and a minimum set of standards need to be defined
	Geospatial Software (open vs propriety) *Good – use a variety of software, providing software resiliency*	*None*
	Duplication of content - *Identified several courses offering similar content.* ***Fragmentation -*** *Fragmentation of topics and lack of clarity of depth of topics or skills* ***Gaps -*** We identified some gaps in the curriculum	*Need to consolidate similar content.* *Need to clarify depth of topics and evaluate.* *Need to develop new courses to add to the curriculum to cover knowledge gaps.*
	Core courses - *Cover a large range of topics some of which are complex topics/skills.* *Newer technologies, data sources and methodologies not visible or not covered*	*Need to re-organise and design.* *New information sources, technologies and methodologies need to be made more visible. Scripting and programming are essential and needs to become part of the core.*
	Internationalisation *Some topics and case study's capture Internationalisation. Not explicitly captured.*	*Additional exploration will be needed to make this visible in the content. Explore how to evaluate or monitor.*

In our analysis and evaluation, we predominantly examined the relationships between courses and identified gaps or redundant topics and evaluated these in combination with the input we gathered from our professional advisory board and our internship hosts. During workshops and interactive sessions, we identified challenges associated with changes in the curriculum and barriers to developing and delivering multi-modal learning environments.

4 SUMMARY AND ACKNOWLEDGMENTS

The most reassuring logical outcome of our evaluation was that the input from our current students and alumni matched very well with that from the organizations interested to hire our graduates. There is a consensus that the programme should invest more in, for instance, learning at least one programming language and should also offer space for professional development skills, such as communication skills and project management. This analysis and evaluation provided us with the necessary input to move into the design and implementation phases and enable us to make choices on which should become, for instance, mandatory subjects in the curriculum.

Challenges - We are in a perfect storm of change where technological advancements are changing how we work, teach and learn. Change is never easy and based on the psychology of change involves five stages (Gatersleben and Appleton 2007, Prochaska, Diclemente, and Norcross 1992): **Pre-contemplation**: lack of awareness of the problem; **Contemplation**: awareness of a problem, but ambivalent about making any changes. Pros and cons of change are perceived as approximately equal resulting in no commitment to change; ***Preparation****: preparing to* commit to make changes. Intent on taking actions to make changes or already starting to make small changes; **Action**: making the change. Accepting the changes needed and taking action for making changes; **Maintenance**: sustaining change. Our goals are to reach a state of maintenance where we can sustain regular ongoing changes to our curriculum. The 5-phase approach we presented here are not only useful for evaluating a course and an academic programme but also provides for management and staff to work through the different phases of change and provide time for reflection as one moves through each of the five stages of change. This also provides programme management opportunities to reflect, monitor progress and identify challenges so that they can aid in preparing for change and develop solutions to support the necessary changes needed.

C*reating an appropriate learning environment, regardless of delivery method (face-to-face, online or blended), requires a significant amount of preparation, planning and design (Palmentieri 2022).* To achieve this requires upskilling of staff and changing how we work. In cooperation with the instructional designers and e-learning staff we have developed workshops and training sessions to enable for staff to improve their didactical skills so that they can adapt their courses for multi-mode learning. This will be an ongoing process that will require continual adjustments to be made. Storyboarding of courses is useful for visualizing courses and can be used for providing suggestions for improvements, focusing discussions and providing suggestions for how to change or create more active learning.
Next steps - We are entering phase 4 – the design phase of our curriculum and programme. We anticipate this will be an ongoing process in the upcoming year. Similar to Phase 3, we are facilitating discussions between staff so that we can consolidate courses, re-organise courses and initiate new course developments to fill knowledge and competency gaps. In addition, we will conduct several pilots that will help us refine our curriculum (see methodology phase 4 for details). Once we have completed phase 4, updates can be implemented (phase 5).

With the recent technological advancements, we now have the ability to provide very rich and multi-dimensional learning environments. To do so requires engineering educational learning environments that will enable us to do so. The inventory of our courses and design of our inventory provides the basis for this. All of our course information is now available in a structured format that makes it easy to search for courses and topics; visualise and analyse content; evaluate content, trends and relationships; evaluate learning activities; and create personal and flexible learning pathways that can link to professional competencies (e.g. (UCGIS)). In summary we can assess what we are teaching and how we are teaching it so that we can make continual and gradual improvements.

5 SUMMARY AND ACKNOWLEDGEMENTS

E-learning team, in particular Janet King (learning designer); all staff at ITC (University of Twente) for their input and participation during workshops; Rob Lemmens; this study was partially funded by UCOW – a Smarter Academic Year.

ABSTRACT

The implementation of sustainable development and the responsible use of the resources available to us are among the key objectives of our time. To meet the challenges of global sustainable development, young professionals with a growing set of skills are needed. Higher education is crucial in fostering the skills graduates need to become agents of change for sustainable development. Therefore, new teaching and learning approaches are needed in engineering education that link technical and sustainability-oriented topics and integrate education for sustainable development (ESD). Studies show that there is a particular lack in the design and implementation of engineering courses that address the close connection between technical and sustainability-oriented issues and contribute to the promotion of the new required competencies. This paper addresses this gap, in which the authors present a teaching example for sustainable engineering education. The article presents the implementation process of a research-based concept. The aim of the module is to expand and strengthen students' competences in the field of sustainability. Various didactic teaching and learning methods were used. Thus, an attempt was made to

combine learning aspects from education, sustainability and engineering and thus to ensure more sustainability in engineering education. The article provides an overview of the structure and the most important components of the module. The knowledge gained will contribute to the evidence-based implementation of sustainability in the engineering sciences. The presented findings should serve as a basis for discussion for the community and contribute to the further development of teaching concepts for sustainable-technical education.

1 INTRODUCTION

The implementation of sustainable development and the responsible use of the resources available to us are among the key objectives of our time. Higher education is crucial in fostering the skills graduates need to become agents of change for sustainable development [1]. Therefore, new teaching and learning approaches are needed in engineering education that link technical and sustainability-oriented topics and integrate ESD [2]. Studies [2-6] show that there is a particular lack in the design and implementation of engineering courses that address the close connection between technical and sustainability-oriented issues and contribute to the promotion of the new required competences.

This is where this paper starts by working with two research questions:

> ***(1)*** How are sustainability issues currently represented in engineering education research (EER)?
>
> ***(2)*** How can a theory-based concept for the integration of sustainability issues in engineering look like and how can it be implemented?

In the sense of design-based work, the pursuit of these two research questions provides both a contribution to the research landscape of engineering sciences and a contribution to teaching practice. The necessary methodological procedure is described in sec. 2. In order to implement sustainability in study program across the board, concepts must be developed. The level of engineering education research (EER) is relevant for this. Methods and theory-based concepts must be developed to integrate sustainability into the engineering degree program, and these in turn must be integrated into teaching practice. Due to the increasing urgency of the problem, concept development and implementation must proceed in parallel, cf. [7,8].

For research question ***(1)***, an introduction and overview of the integration of sustainability in engineering is given. In section 3, a literature analyse shows to what extent the topic of sustainability is currently addressed in the research landscape of EER and which specific concepts exist that integrate sustainability aspects in engineering education. In this context, an analysis looks at the research landscape in EER to find out to what extent sustainability has been addressed between the years 2014-2018 and 2021. For this purpose, the mention of sustainability in 3,570 conference articles was evaluated. As a result of that survey, it becomes clear that there is a research gap especially in the development of theory-based teaching concepts for linking sustainability and engineering.

To answer question ***(2)***, this research gap will be addressed. In section 4, an exemplary teaching-learning concept is developed and transferred into practice. The aim is to develop an interdisciplinary concept that enables the integration of sustainability topics into the engineering sciences in order to promote sustainable development. The elective module was carried out in the Master's degree program " Management & Engineering" in the winter semester 2022/2023 at Leuphana University. Section 4 describes the learning objectives as well as the developed concept, first student feedback is evaluated. The concept is intended to serve as a guideline that enables other engineering program or universities to implement a similar module and simplifies the integration of sustainability topics into the engineering sciences.

2 METHODOLOGY

“Methodology can be seen as the strategy, the plan of action, process or design lying behind the choice and use of particular methods and linking a choice and the use of methods to the desired outcomes” [9]. For a successful completion of the research question it is necessary to clarify the connection between the research goals and the selected methodology. The research objectives in this article are standing for both, theoretical understanding and educational practice. In order to design and to study within the same research process (see [10]) we´ve chosen design based research. Design based research is a multi-faceted approach that "...can yield valuable results for both theoretical understanding and educational practice" [10]. The generic model for educational design research is shown in fig.1. This methodology has also been used because the main stages of the research interact with the educational practice. In this way we were able to achieve our research objective by dual outputs of innovative approaches and theoretical findings. Fig.1 presents the three stages of the process model for the design based research: Analysis, Design and Evaluation. All three stages are implemented in the research process and are explained below.

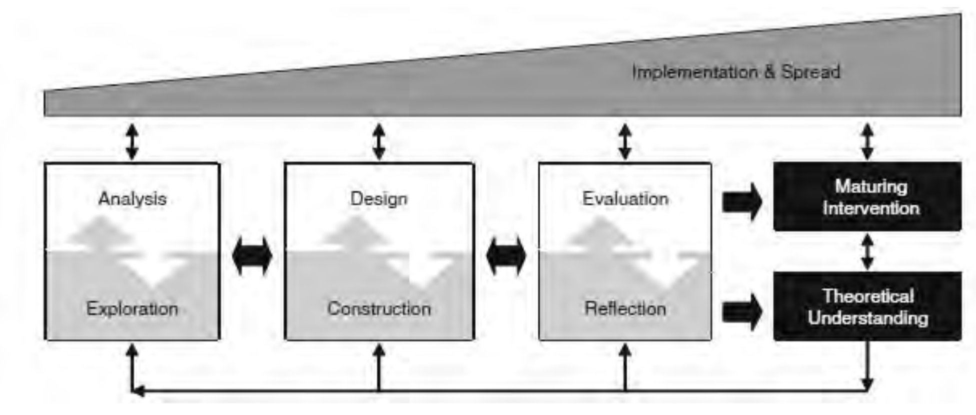

Fig.1. Generic model for conducting educational design research [11]

Within the ***analysis phase*** we surveyed the EER landscape. The result is a research-guided category system consisting of ten main categories and 78 subcategories that encompasses the essential aspects of the research field, their specification, and the relationships and delimitations of the individual categories to one another (exemplified by the example of sustainability in Section 3). General statements of the overall analysis are given in [3], the results with a focus on linking sustainability and engineering are presented in section 3. For the purpose of gaining knowledge at the interface of engineering and sustainability, two leading IEEE conferences of the international EER research landscape, the FIE and EDUCON, were selected as the basis for the systematisation, whose publications appear annually in a two-stage blind review process. With the aim of an international and up-to-date analysis, contributions to EDUCON and FIE from the years 2014 to 2018 and 2021 (EDUCON only) were systematically analysed and categorised using a catalogue of categories developed in advance. In doing so, EDUCON, like SEFI Annual conferences, focuses more on the European research landscape, while FIE expands the research work to include a more international (especially american) view. This approach addresses the critiques of [12-14], who point to existing disciplinary and geographical divisions in the research landscape. Although the research presented does not provide a complete overview, basic statements and research trends on sustainable engineering education can be derived. The number of articles from the respective years that were used to categorise the scientific articles is presented in Tab. 1.

Table 1. Number of published and categorised papers of the international EER conferences Global Engineering Education Conference (EDUCON) and Frontiers in Education Conference (FIE) in the years 2014 - 2021, own data.

Year	EDUCON	FIE	Total
2014	196	519	715
2015	154	403	557
2016	191	410	601
2017	289	306	595
2018	300	537	837
2021	265	-	265
Total number of categorised paper			**3,570**

Based on the findings we next turned our attention to the development and the implementation of a theory-based concept to embed sustainability in the engineering curriculum, worked out in section 4.1 and 4.2. This ***design stage*** of the design-based research process was followed by evaluation process. To register statements about students understanding and feedback to the module an ***evaluation*** was undertaken, that results of which are presented in section 4.3..

3 ANALYSIS OF THE EER-LANDSCAPE REGARDING SUSTAINABILITY

The total of 3,570 FIE and EDUCON conference articles from 2014-18 and 2021 (EDUCON only) were each assigned a minimum of one and a maximum of two main and sub-categories. A total of 6,627 categories were assigned. What is noticeable in the overview of the results of the category allocation is the lower number of allocations in the contributions to EDUCON, which can be attributed to the different absolute number of contributions to the respective conference (see Tab. 1). In both conferences, topics in the context of teaching and learning processes were addressed most frequently by far. For limited reasons, a more comprehensive overall evaluation is not included in this paper, as the focus is on the evaluation of the topic area of sustainability. The category "Topics related to Engineering" as one of the 10 main categories categorises publications that place the thematic focus on topics that are not subject-specific but are related to engineering content [3]. One of the subcategories belonging to this main category is “Sustainability”. In the following, the number of contributions dealing with the topic of sustainability is quantitatively highlighted. The results are analysed qualitatively.

Fig.2 gives an overview of the categorisations of the articles of the FIE and EDUCON to the sub-category sustainability over the years. Out of a total of 6,627 categorisations, 48 (0.72%) were made in the sub-category "Sustainability". By way of explanation, it should be added that a category is only awarded if the *majority of the contribution* deals with the theme. Most articles were sighted in 2017. In general, the proportion of articles that address the topic of sustainability is extremely low at 0.72%, which illustrates and supports the situation described in the introduction. Contrary to expectations, there is no trend to be noted in the results.

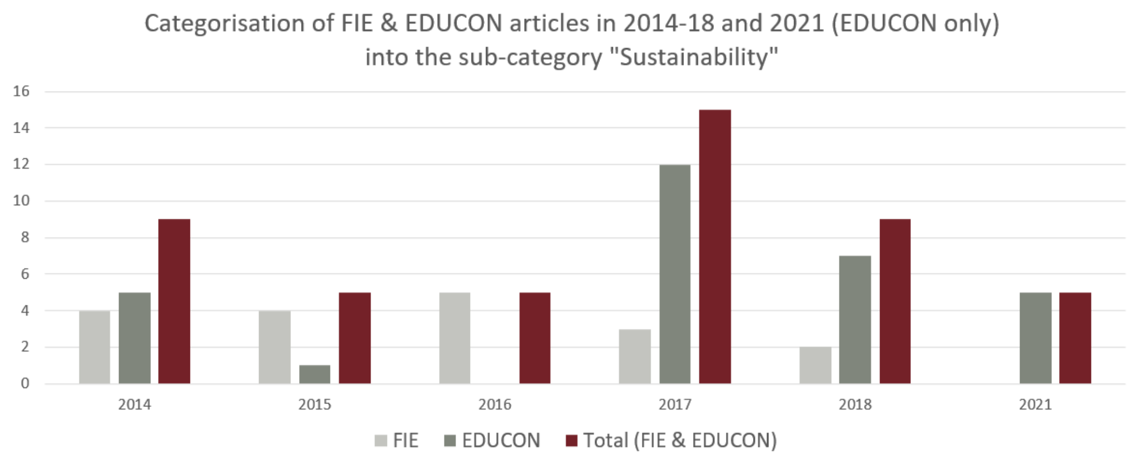

Fig.2. Categorisation of FIE & EDUCON conference articles in 2014-18 and 2021 (EDUCON only) into the sub-category “Sustainability”, own data

In order to find out whether the topic of sustainability nevertheless plays a role in the categorised articles, a "COUNT IF" query was carried out in Excel. It was analysed how often the word "sustainability" was written in the title (9 times), in the keywords (20 times) and in the abstract (39 times). In addition, the words "sustainable" and "climate change" were filtered. The word "sustainable" appeared in a total of 18 out of 3,570 titles, in 17 keywords and 55 abstracts. "Climate Change", on the other hand, was only mentioned once in the title and keywords and three times in the abstract. The occurrence of the word "sustainable" should be interpreted with caution, as it refers not only to sustainability aspects, but also, for example, to long-lasting projects that do not directly include sustainability issues. With a total of only five mentions, the occurrence of the word "climate change" can be neglected. Fig.3 shows the frequency of the word "sustainability" in the title, abstract and keywords depending on the year.

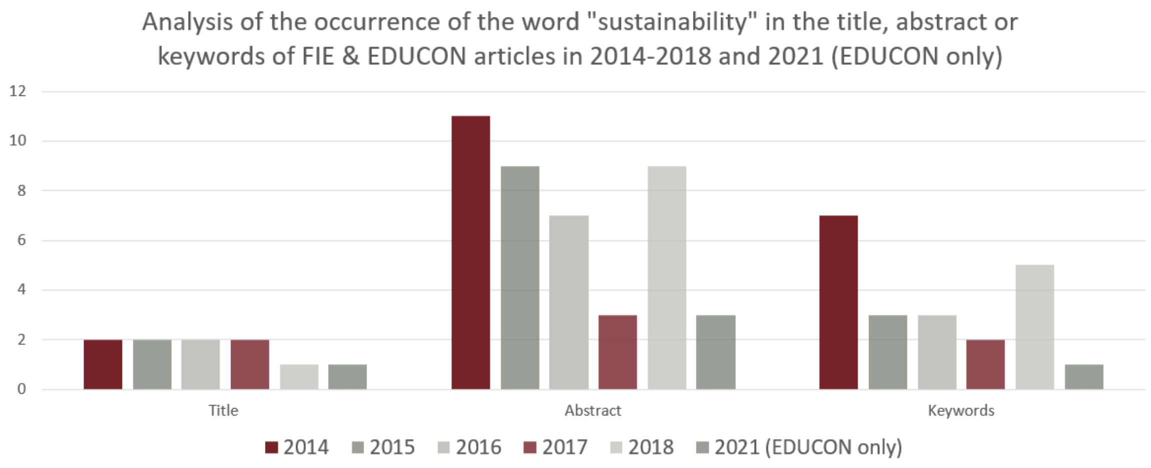

Fig.3. Analysis of the occurrence of the word "sustainability" in the title, abstract or keywords on FIE & EDUCON conference articles in 2014-18 and 2021 (EDUCON only), own data

The latter analysis confirms the results of the categorisation, as the frequency of the keywords is in similar dimensions to the allocation of the articles. Basically, however, it becomes apparent that very little relevance is attributed to the topic of sustainability in engineering education research and practice, which urgently needs to be changed. An approach for integrating sustainability aspects in engineering education is therefore presented in the following chapter.

4 THEORY-BASED THEACHING CONCEPT FOR SUSTAINABLE ENGINEERING EDUCATION

In order to anchor sustainability aspects in the teaching of engineering and to strengthen the students' awareness, especially in the area of social and ecological sustainability, a teaching-learning concept was developed based on the theoretical findings of the analysis and constructivist learning approaches, e.g. [15].

4.1 Teaching concept for sustainable competences in engineering

The developed concept for sustainable competences in engineering is shown in Fig. 4. It consists of a triad of a content level, a methodological-didactic concept and an individual process level. With the concept, a structured program development is designed that promotes the teaching of sustainability aspects in an engineering context, can be flexibly adapted to the interest of the students and involves the participants in the design of the module through the flipped classroom approach. On the ***content level***, the technical basics in the areas of sustainability science and didactics are first taught. The Blue Engineering Concept [16] is included in this. By participating in the first thematic teaching-learning modules, students should begin to understand the interactions. Through the selection and implementation of an existing

Blue Engineering module as well as the subsequent deepening of the content of a self-selected topic, the participants should acquire professional basics.

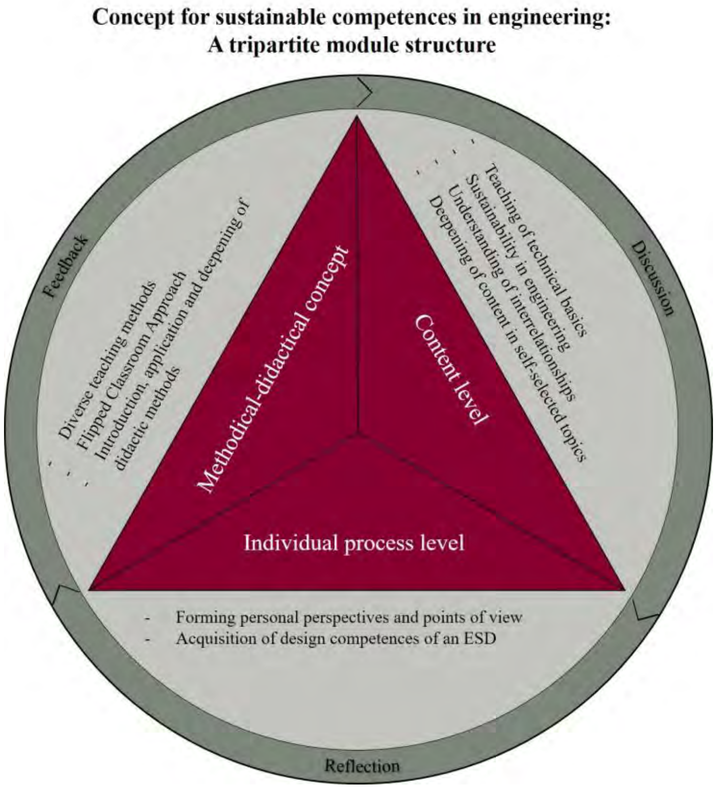

Fig.4. Teaching concept for sustainable competences in engineering

For a successful ***methodological-didactic concept***, a variety of learning methods are to be used. Personal perspectives and points of view should be developed and enable participants to act. The acquisition of factual and methodological competence, social competence and self-competence on an ***individual level*** should take place.

4.2 Implementation

The 5 CP module "Sustainable (Blue) Engineering" was designed for 15 participants and offered in winter semester 2022/2023. The learning group consists of students of the Master's program "Management & Engineering" at Leuphana University. The biweekly 3.5-hour course was structured as follows, so that a step-by-step approach and deepening of the interplay between technology and sustainability was possible:

- **Teaching the basics in the subject area of sustainability in the engineering sciences (**Introduction to didactic methods and feedback rules, Introduction to Sustainability Science, Participation in initial teaching-learning modules)
- **Application of the basics in the subject area of sustainability in the engineering sciences (**Application of didactic methods and feedback rules, Teaching content on the topic of engineering and sustainability, Preparation and implementation of existing Blue Engineering teaching-learning modules)

- **Exemplary deepening through the development of own teaching-learning modules (**Choice of didactic methods for teaching the chosen topic, Examination of the content of self-selected topics, Implementation of the self-developed teaching-learning modules)

4.3 First findings and feedback

At this point, the first findings of the evaluation are presented, in particular the participants' feedback on the course. It should be noted that the evaluation is not to be understood in the sense of a complex effectiveness analysis, but rather aims to provide insights into initial implementation experiences and student feedback on the implementation of the program. A selection of the student feedback is shown in Fig. 5. The results show that the students are very satisfied with the course and their knowledge gain and that the module motivates them to engage with and reflect on the topic. In general, these statements can be considered as implementation success. Further findings can be presented at the SEFI 2023 conference.

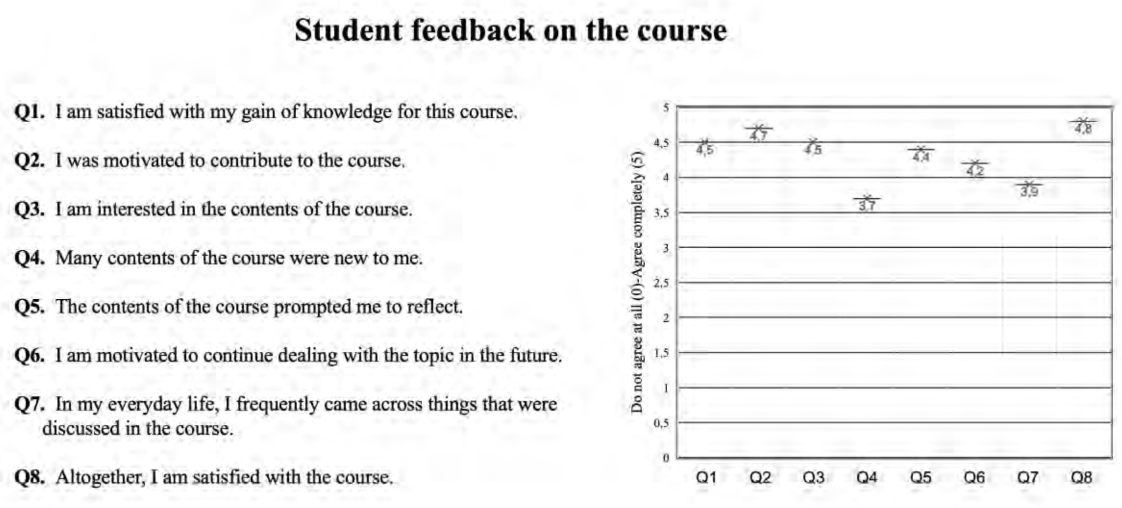

Fig.5. Student Feedback on the Course (own data)

5 SUMMARY

The paper provides research-based evidence that the topic of sustainability has so far been underrepresented in engineering, which is why evidence-based interdisciplinary implementation procedures, as presented in Section 4, are highly relevant. An interdisciplinary approach has been developed and implemented in educational practice. The course received positive feedback from participants and allowed for knowledge growth. Further module runs are planned in the coming semesters in order to continuously evaluate, adapt and optimize the developed concept.

ABSTRACT

Today's society is impacted by complex, fast and continuously changing problems. These need to be tackled inter-, multi and transdisciplinary. At the University of Twente, we have developed a new CBL minor *Intelligence, creativity, and responsible technological innovation in societal transformations*, (ICR&TIST), which focuses on research skills in complex socio-technological problem-solving contexts. The design of this minor has been guided by new insights from long-running research aimed at developing a *Philosophy of Science for the Engineering Sciences* and extensive experiences with engineering education in project-based learning (PjBL).

Education in scientific research tends to focus on academic contexts, while scientific research in real-world problem-contexts (e.g., sustainability) requires the ability to effectively and responsibly construct relevant, reliable and intelligible knowledge for the benefit of the concrete, local problem and possible solutions, using everything science has to offer (knowledge, methods, instruments, mathematical tools). This type of scientific research calls for a *new paradigm*, called an *engineering paradigm of science*. *Conceptual modelling* (rather than hypothesis testing) fits better the core activity of this type of scientific research and should therefore be seen as an overarching skill.

The educational design of the minor has adopted conceptual modelling as the overarching learning objective. This new concept, how to work with the accompanying conceptual modelling methodology (B&K method) and understand the underlying philosophical insights appears exciting and challenging for the multi-disciplinary educational-design team. This paper will elaborate on the educational design process, the resulting design of the minor, and preliminary findings in the pilot-phase.

1 INTRODUCTION

1.1 Conceptual modelling as research skill in socio-technological problems

Today's society faces complex and rapidly evolving problems that require interdisciplinary approaches. At the University of Twente, we have developed the *Intelligence, creativity, and responsible technological innovation in societal transformations* (ICR&TIST) minor, which focuses on research skills in socio-technological problem-solving contexts. This paper introduces conceptual modelling (CM) as a research skill suited for complex real-world problem-contexts, such as sustainability. By effectively and responsibly constructing relevant and reliable knowledge, CM enables the utilization of scientific resources. The changing paradigm of science, specifically the engineering paradigm, is discussed in relation to CM, along with the B&K method for constructing and analyzing conceptual models. The implementation of CM as an overarching research skill in engineering education is highlighted, along with the identified barriers that require further investigation.

1.2 Research in the engineering science: experiences and insights

The author's background in chemical engineering and *process optimization research in industrial bioleaching processes* (e.g., Boon 1996a, Boon and Heijnen1998) aimed at developing *sustainable technologies* has acted as a moral and epistemological concern that motivated philosophical inquiry. For example, a contribution to a book about sustainable futures raises questions about the role of (academic) scientific research:

> “In discussions about the relation between science and sustainability at least four questions come to the fore. (1) What should be the role of science in a society aiming at sustainability? (2) Is science as practised today appropriate for a sustainable society? (3) Do we have indications that point at the emergence of new methodologies and paradigms relevant for the realization of sustainability? (4) Can we come up with proposals for eliminating or creating (un)favourable conditions for the role of a new science in a sustainable society?” (Boon and Doorman 1994).

The *normative epistemological* focus in developing a *philosophy of science for the engineering sciences* (Boon since 2001) therefore primarily concerns the *quality of scientific research and education practices* in view of their societal contributions (e.g., to sustainability), where *ethics in technology* acts in the background.

Philosophical reflection during the research project, shed light on several challenges regarding the role of science, including the difficulty in integrating fundamental scientific knowledge and misaligned expectations between technologists and microbiologists. Furthermore, the lack of deeper scientific understanding in industrial research and the translation of concepts without considering scientific understanding are highlighted. The tension between publishing academic articles conforming to reductionist research methodologies and generating practical scientific understanding for industry is also discussed. These experiences contribute to the identification of a gap between fundamental and applied research, leading to the realization that expectations of scientific research do not always align with practical and societal needs.

1.3 Overview

The paper briefly explains the importance of philosophy of science for the engineering sciences in bridging the gap between fundamental and applied research. By critically reflecting on the value and relevance of scientific research for reliable, relevant and responsible knowledge production in socio-technological contexts, philosophy helps reshape research approaches and education therein.

The paper then moves on to discuss aspects of the *philosophy of science for the engineering sciences* that underpins the proposed interpretation of conceptual modelling. This includes replacing the *traditional physics paradigm* by an *engineering paradigm of science*, better suited for understanding the role of scientific research in addressing complex socio-technological problems.

The engineering paradigm of science emphasizes, among other things, the production of *relevant, reliable and useful knowledge* as a goal of scientific research. Regarding the *quality of scientific research practices*, this implies for example that, in contrast to emphasis on universal knowledge and reductionism in the physics paradigm, the focus should be on the construction of relevant and reliable knowledge (including technological and mathematical tools) for specific problems. This normative basis raises the epistemological question of what this implies for scientific research and teaching practices. The engineering paradigm emphasizes that conventional reductionist approaches are not necessarily the best, and relatedly, that applying fundamental scientific knowledge is less straightforward than the physics paradigm suggests. In addition, *interdisciplinary research* is crucial for knowledge production for real-world contexts, which is notoriously difficult and not straightforward either. Conceptual modeling aligns with this paradigm and provides a framework for effectively addressing complex problems in scientific research projects.

To further develop the quality of academic engineering education, the paper suggests conceptual modelling as an overarching learning objective that contributes to the ability of engineers in professional roles to conduct scientific research in complex socio-technological context. The B&K method, which aids in the construction and analysis of conceptual models, is explained in detail. Finally, the paper briefly discusses the educational design of the (30 ECTS) ICR&TIST minor.

2 PHILOSOPHY OF SCIENCE FOR THE ENGINEERING SCIENCES

The philosophy of science examines beliefs and views about science and their impact on research practices. Commonly, ideas about science are influenced by physics as an example of "real" science. However, it is essential to determine if these ideas are suitable for the engineering sciences or if they hinder problem analysis and solutions. Based on my experiences in the engineering sciences, I hypothesized that our current ideas about science justify research practices but may not always be productive as desired (Boon 1996a, 1996b, 2006, 2011a). Therefore, an alternative understanding of science is necessary, specifically a paradigm of science that better suits the engineering sciences (Boon 2017). Developing a philosophy of science for the engineering sciences has been a focus of my research for the past twenty years.

In typical discussions about science, the emphasis is primarily on evidence for scientific claims, which is evident in scientific articles and how they are read and taught. The content and methodologies of science education revolve around conveying proven scientific knowledge and evidence-oriented research methodologies like hypothesis testing. Students are often taught to critically assess whether the methodology and collected data sufficiently support the conclusion. The philosophy of science uses the term "context of justification" to describe this focus on evidence. The “context of discovery,” on the other hand, encompasses aspects like creative thinking, formation of concepts, understanding and conceptualization, and various reasoning processes that cannot be considered as evidence.

These discussions reveal several important assumptions about scientific research. Firstly, the normative claim that evidence for scientific claims should solely consist of objective data and logically valid arguments. Secondly, the metaphysical belief that such evidence provides certainty or proof of the (approximate) truth of scientific claims. Thirdly, the belief that the goal of science is to produce true claims about physical reality. Lastly, the epistemological belief that true knowledge about specific instances can be deduced from proven scientific claims. These assumptions are part of a paradigm of science called the *physics paradigm*.

However, contemporary philosophy of science and historical case analysis have shown that these assumptions are philosophically problematic and inadequate in representing successful scientific practices (e.g., Knuuttila and Boon 2011). The dominant physics paradigm often overlooks crucial aspects of scientific research, particularly in applied sciences like the engineering sciences. As a result, an alternative paradigm of science, termed the *engineering paradigm*, is necessary. The engineering paradigm emphasizes that the construction of knowledge is an inseparable part of understanding and justifying scientific knowledge claims (Boon and Knuuttila 2009). It challenges the unjust distinction between the context of discovery and the context of justification and proposes the "context of construction" as an alternative (Boon 2022).

Thomas Kuhn (1962) introduced the concept of paradigms and paradigm shifts in science. A paradigm encompasses symbolic generalizations, metaphysical presuppositions, values to judge theories, and exemplars (Kuhn 1970). Inspired by Kuhn's work, contrasting paradigms of science have been developed: the physics paradigm and the engineering paradigm (Boon 2017). These paradigms allow for the examination of differing beliefs about science. For example, the engineering paradigm focuses on constructing useful knowledge for specific applications, while the physics paradigm assumes the discovery of pre-existing entities and phenomena.

The engineering paradigm has implications for ideas about scientific knowledge, methodology, and education. It recognizes the roles of technological instruments and human understanding in generating and interpreting data. Scientific knowledge is seen as representations of human understanding, constructed using empirical knowledge, measurement tools, scientific concepts, theories, and mathematics. The engineering paradigm acknowledges the contributions of conceptual and instrumental resources in scientific knowledge construction, which the physics paradigm tends to ignore.

The alternative engineering paradigm of science has profound implications for conceptual modeling and provides a richer understanding of its meaning.

3 CONCEPTUAL MODELLING

The term 'conceptual modelling' is not new. Robinson (2008), for example, stresses the importance of conceptual modelling for (computer) simulation, while Thalheim (2010, 2012) declares that conceptual modelling is one of the central activities in computer science. It involves creating schematic descriptions of systems, theories, or phenomena using concepts to enhance the model. However, these authors also consider conceptual modelling the most difficult and least understood aspect of e.g. computer simulation studies.

There are three types of scientific models: those deduced from abstract theories, visually represented models of unobservable entities, and heuristic models used as aids. The first type aligns with the physics paradigm, where the model is derived logically or mathematically from the theory. The second type represents invisible entities or phenomena and relies on the similarity between the model and the real-world entity. The third type, heuristic models, are not intended to be realistic but serve as tools.

In an engineering paradigm, models are not literal representations but rather how researchers imagine and conceptualize the (invisible) phenomenon. These models contain essential information expressed verbally and visually, making them *thinking tools* (called *epistemic tools*) within a specific context. Models (esp. conceptual models) are thus considered *epistemic tools* that help researchers think about and interact with the phenomenon they represent, as well as the ever further development of these models (Boon and Knuuttila 2009).

To illustrate this view on models, the example of Sadi Carnot's conceptual modelling of the ideal heat engine is presented (Knuuttila and Boon 2011). Carnot's model was constructed based on already existing steam engines, aiming to understand the limits of power generation from heat (Carnot 1824). His approach involved abstracting from the technology and formulating the problem more fundamentally. Carnot's model included both abstract and practical concepts, as well as fundamental principles and existing scientific knowledge (e.g., gas-laws).

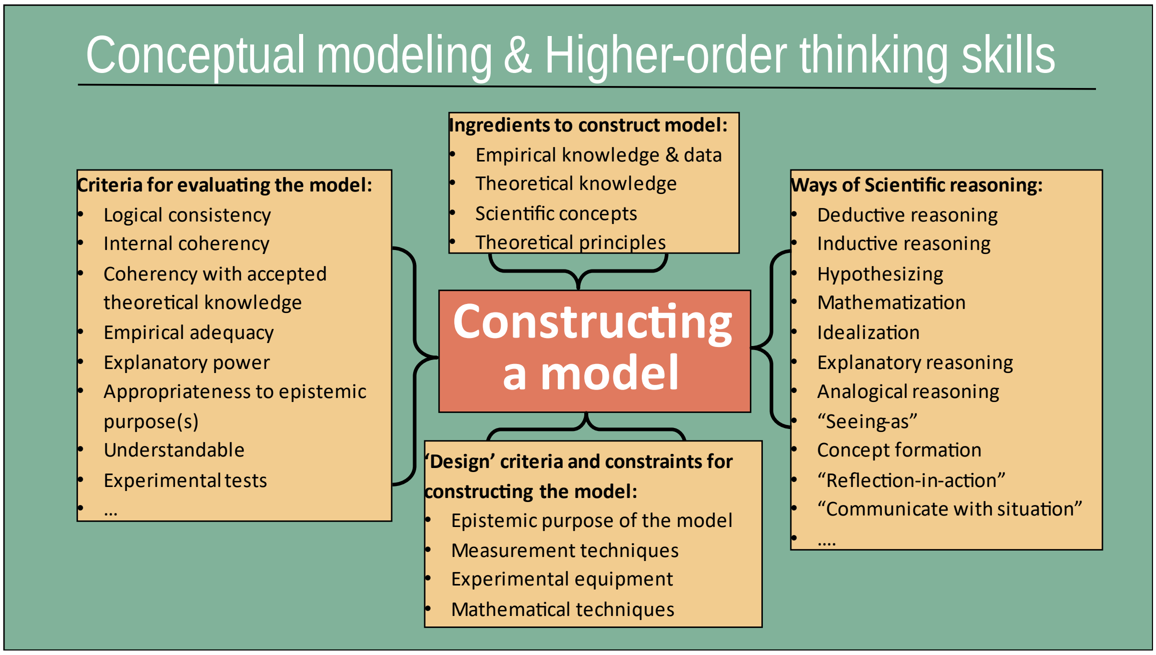

Figure 1 (Lecture slide, copy right Mieke Boon): Conceptual modelling according to an engineering paradigm of science. 'Reflection-in-action' and 'Communicate with the situation' in the scientific reasoning box (right side) refers to Schön (1983).

The B&K method, consisting of ten questions, can be used to systematically determine the aspects built into a scientific model. It helps construct or reconstruct existing models by considering relevant elements (partly listed in Fig. 1, upper and lower box). However, the B&K method is not an algorithm but a tool that requires scientific reasoning skills (Fig 1, right box) and epistemic responsibility (Boon 2020a) guided by criteria (Fig 1, left box) relevant to the intended epistemic purpose of the model.

The engineering paradigm recognizes that an algorithmic methodology for producing true or correct knowledge is not feasible. Researchers bear the responsibility of deciding which ingredients to include in the model, considering the available resources, existing knowledge, and the model's epistemic purpose (Boon and Van

Baalen 2019). This approach does not compromise objectivity and rationality but involves meeting logical, epistemic, and utility criteria (Fig. 1, box left).

“Bringing the human back into science” is an essential aspect of the engineering paradigm (Boon 2020c). It acknowledges the role of human scientific reasoning, which extends beyond logical reasoning (Fig. 1, box right). Researchers must develop higher-order thinking skills (HOTS) and engage in critical assessment of models, including the criteria used (Fig. 1, box left) and how well the models meet them.

In summary, conceptual modelling plays a central role in scientific knowledge construction. It requires intellectual skills and training in higher-order thinking for researchers. The engineering paradigm embraces the complexity of conceptual modelling and emphasizes the responsibility of researchers in constructing and evaluating models.

4 TEACHING AND LEARNING CONCEPTUAL MODELLING

4.1 Conceptual modelling interpreted from the engineering paradigm

The traditional physics paradigm of science, which emphasizes objectivity, rationality, and the pursuit of true knowledge, has influenced engineering education in unproductive ways. It limits the recognition of the human role in scientific research and overlooks the diverse ways of reasoning that contribute to scientific understanding. Academic engineering education has also adopted some of these ideas, such as the distinction between research and design and the limited roles attributed to teachers in supporting the development of HOTS by students in scientific research (Boon 2022). However, the engineering paradigm offers a different perspective, emphasizing the importance of the human ability of conducting scientific research in complex problem-solving contexts, which involves the human ability to reason in different kinds of ways (Fig 1, box right) and judge the quality (Fig 1, box left) of conceptual models thus produced.

Conceptual modelling, as interpreted from the engineering paradigm, provides a suitable approach for teaching and learning scientific research in academic engineering education. It involves understanding conceptual models as representations of researchers' understanding of a phenomenon, incorporating various contributions from technology, mathematics, and cognition, and being constructed with specific epistemic purposes in mind. Conceptual modelling serves as an overarching learning objective that involves developing other intellectual skills (Boon et al. 2022). According to the engineering paradigm, these include (non-exhaustive): problem-analysis, systems-thinking, knowledge-application, integration of heterogeneous elements, explanation, evaluation, representation, conceptualization, and logical reasoning.

4.2 Implementing conceptual modelling in academic engineering education

There are several ways to implement conceptual modelling in engineering education:

1. *Explaining abstract theory*: By reconstructing the development of a theory, such as thermodynamics or electro-chemistry, students can gain a deep understanding of its structure and content (e.g., Knuuttila and Boon 2011). The B&K method provides guidance for analyzing and identifying key components. This understanding enables students to apply the theory effectively in practical applications (Orozco et al. 2022, 2023).

2. *Analyzing scientific articles*: The B&K method can be used to analyze scientific articles, allowing students to gain insight into the content and identify important aspects of the reported research (Boon 2020a). This approach helps students overcome the challenges of reading scientific literature and encourages them to focus on the research process rather than just the conclusions.

3. *Using conceptual modelling in PjBL and CBL projects*: Conceptual modelling can be implemented as an overarching approach in problem-based and challenge-based learning (PjBL and CBL) projects (Boon 2020a). By constructing conceptual models of complex problems, students can develop a deeper understanding of the problem and the criteria for potential solutions. The B&K method provides support for students' modelling activities in these projects.

Implementing conceptual modelling in engineering education has shown positive outcomes. Teachers have observed improvements in the quality of student projects, and students have expressed an understanding of how conceptual modelling supports their research. However, students often struggle with thinking like researchers and formulating research questions. Further scaffolding is needed to develop their higher-order thinking skills, particularly in question-asking as part of the conceptual modelling proces (Orozco 2023).

In summary, teaching and learning conceptual modelling in academic engineering education aligns with the engineering paradigm of science. By implementing conceptual modelling in various educational contexts, students can develop a deeper understanding of scientific research and enhance their ability to responsibly produce relevant and reliable knowledge (including instruments and tools) for complex socio-technological problems.

4.3 Educational design of the ICR&TIST minor

The overarching learning objective of the ICR&TIST minor is to conduct trans- and interdisciplinary research. The educational design adopts a challenge-based-research-learning (CBR/L) approach in which students learn to conduct trans- and interdisciplinary research on a complex real-world problem. To this end, we have entered into a partnership with external stakeholders in the *energy-transition challenge*. Crucially, this minor is entirely skills-oriented (rather than content- oriented as in most programs focused on interdisciplinarity, see Kuiphuis-Aagten et al. 2019).

The development of so-called higher-order-thinking skills (HOTS) relevant to trans- and interdisciplinary research is promoted by eight inter-related micro-modules (1 ECTS each). The minor and micro-modules have been developed by a multi-disciplinary cross-faculty team of dedicated teachers and educational designers. The micro-modules cover conceptual modelling through the B&K method, and seven other micro-modules aimed at understanding methods and measuments in both the engineering and the social sciences, developing ‘the art of reflection’ targeting critical thinking, creativity, problem-analysis, and responsibility (also see Schön 1983), and insights into research-strategies in inter-and transdisciplinary research. For the multi-disciplinary teacher-team in our educational-design team, this new concept, how to work with the accompanying CM methodology and understand the underlying philosophical insights is exciting and challenging: "this is a completely new paradigm of what scientific inquiry is and our roles as teachers."

5 CONCLUDING REMARKS

The University of Twente recently developed a challenge-based learning (CBL) minor called *Intelligence, creativity, and responsible technological innovation in societal transformations* (ICR&TIST). This interdisciplinary program aims to cultivate scientific research skills in complex socio-technological problem-solving contexts. The educational design of the minor incorporates the engineering paradigm of science and draws on experiences with the conceptual modelling approach in project-based learning (PjBL).

The current problem is that scientific research training typically focuses on academic contexts, aligned with the physics paradigm of science. However, real-world problem-solving requires the ability to produce relevant, reliable, and understandable knowledge in concrete problem contexts, utilizing the full range of scientific resources available. Additionally, socio-technological problems necessitate trans- and interdisciplinary research, which is intellectually challenging (Boon 2020b).

The goal of the CBL minor is to foster students' trans- and interdisciplinary research skills, with a particular emphasis on interdisciplinary research skills (cf., Van den Beemt et al. 2020, Boon and Van Baalen 2019, Boon 2020b). Existing interdisciplinary PjBL and CBL education primarily focuses on scientific content and professional skills development, with limited support for promoting interdisciplinary research skills (Kuiphuis-Aagten et al. 2019). To address this gap, it is crucial to scaffold students development of higher-order thinking skills required for understanding and conducting scientific research.

A key pedagogical insight is that students struggle to apply abstract knowledge in concrete settings due to the physics paradigm's emphasis on true and justified knowledge. In contrast, the engineering paradigm highlights the application of scientific knowledge in problem-solving contexts and the understanding of how knowledge is *constructed*. Therefore, it is essential to prioritize the development of scientific thinking skills over the conveyance of scientific content. Students with these skills can acquire knowledge independently, prompting teachers to reflect on their contribution to students' scientific thinking skills.

Another insight is that both students and teachers are influenced by the physics paradigm, shaping their beliefs and attitudes about teaching and learning. Paradigm shifts, as described by Kuhn, are challenging and require time. Redesigning education using the conceptual modelling approach necessitates creating awareness of paradigms among teachers and students.

The design process of the ICR&TIST minor involved workshops with the teacher team, where strategies such as reflecting on crucial learning experiences were employed. Teachers' beliefs about scientific research and education were interpreted from the physics versus engineering paradigm to increase awareness of paradigms. This process facilitated the development of shared understandings and led to the joint creation of micromodules, aiming to promote scientific thinking skills related to research and measurement methods, including several types of reflection skills.

Educational research on the pilot of this minor is ongoing, but initial findings indicate that teachers found the approach inspiring, experiencing a paradigm shift in their understanding of scientific inquiry and their role as teachers. Students quickly adapted to the new mindset, finding it exciting and liberating. They realized the potential to develop their higher-order thinking skills actively. Scaffolding the development of scientific research and thinking skills based on the engineering paradigm proved successful, although there is room for improvement and further research is needed to identify and address students' obstacles.

In conclusion, experiences in education and insights into the scientific research required for academically trained engineers highlight the need for the development of interdisciplinary research skills to tackle complex socio-technological issues. Conceptual modelling serves as an overarching skill encompassing various other skills, and a scaffold has been developed to facilitate the learning process. The new educational approaches have shown positive results and garnered appreciation from students and teachers. However, students still face challenges in developing the higher-order thinking skills crucial for scientific research. Further research is necessary to identify and address these obstacles, ensuring the effective support of students in becoming creative and responsible researchers, thereby enhancing the quality of academic engineering education.

6 ACKNOWLEDGMENTS

The design and implementation of education in conceptual modelling described in this paper has been developed in collaboration with many teachers, educational support staff and student assistants at the University of Twente, who I wish to thank and acknowledge (alphabetic order): Angelique Assink, Gianluca Ambrosi, Ruchi Bansal, Marike Boertien, Kerensa Broersen, Jan Buitenweg, Luuk Buunk, Leonie Chapel-Bosch, Daniela Craciun, Kees Dorst, Jacqueline Drost, Karin van den Driesche, Janneke Ettema, Ariana Gayardon de Fenoyl, Robert-Jan den Haan, Marie-José Herik, Leonie Krab-Hüsken, Anne Leferink, Miles MacLeod, Leon van de Neut, Mariana Orozco, Deger Ozkaramanli, Ringo Ossewaarde, Kishore Sivakumar, Arturo Susarrey Arce, Sophie Van Baalen, Jan Van der Veen, Klaasjan Visscher.

ABSTRACT

A method to develop Entrepreneurship Education in any regular Engineering course is presented. The method is based in a team of students working on the description of the idea for the development of a real start-up using a structured approach trained by a business advisor and by the teacher. The team analyses the problem, the potential market, the solution, the development and the financing challenges of the start-up. The team works the Case development along an Engineering Course related with the technology of the start-up. The dedication of each student to the Case development is 25 hours, working along the different phases of the analysis and synthesis, mentored by the business advisor and the teacher. The added value of the experience is based on: first, the preparation and development of a 1 hour interview of the student team with one of the founders of the company, usually the CEO; second, a weekly validation of the technological value proposition with the business advisor, as part of the analysis. Along with the interview, the student team will consolidate their findings and debate with the CEO about their own ideas, being a process full of positive adrenaline and creating a very significant engagement along the whole course. The approach has been tested in two academic years, working 4 cases with the collaboration of 4 start-ups of EIT InnoEnergy. The results of the student surveys demonstrate the validity and engagement level of the approach.

1 INTRODUCTION

1.1 The objective that is addressed

This paper is aligned with the objectives of the European Institute of Innovation & Technology (EIT), a body of the European Union, and the ambition to create a positive impact for our society. An extract of the EIT Vision: “...is to become the leading European initiative that empowers innovators and entrepreneurs to develop world-class solutions to societal challenges and creates growth and skilled jobs.”

The paper is focused on developing a new method for entrepreneurship education, capable of generating more and better impact in the creation of start-ups, even in the short term. The new method that is presented here has been developed because of the opportunities generated by the collaboration of the authors and EIT InnoEnergy, an alliance that incorporated companies, start-ups, universities, research centres, business schools, business advisors and more stakeholders.

1.2 The context for the development

The topic of entrepreneurship education has attracted a lot of attention and has generated significant contributions in recent years. A fundamental view about the nature of entrepreneurship and the skills of an entrepreneur is stated by (Gartner

1988): an entrepreneur is characterised for creating organisations. A comprehensive review of methods and approaches in entrepreneurship education is given in (Gartner and Vesper 1994). The “standard” course includes elements such as business model writing, speakers, readings and cases. All in all, offering basic tools and a number of practical experiences to create background and developing skills. Frequently, judging panels including outside professionals assess the work of the students.

(Liñán and Fayolle 2015) deals with a key factor recently identified in entrepreneurship education: entrepreneurial intention. The research highlights five factors: the model, the influence of personal variables, entrepreneurship education, the context, the entrepreneurial process and the intention. (Kirby 2004) states about the relevance of educating “for” entrepreneurship, instead of educating “about” entrepreneurship, the ultimate goal is to focus on student centered approaches.

When talking about student centered methods, a fundamental work to be considered is (Dewey 1986). The essence of the proposal is to use direct experience as the fundamental engaging approach in education.

A relevant contribution on the student centered approach applied to entrepreneurship education is (Robinson, Neergaard, Tanggaard and Krueger 2016). This paper, based on an ethnographic approach, focuses on the pre-foundation phase, as original when compared with the typical approach analysing the post-foundation phase.

The method presented in this paper integrates the different approaches in the literature listed above with the specific opportunities of the EIT InnoEnergy alliance.

2 METHODOLOGY

2.1 Description of the method

The method presented in this paper incorporates some fundamental principles identified in previous research and own contributions:

1. The capacity of the students to become entrepreneurs (create an organisation) after the experience in the course.
2. The course should work on basic topics like the analysis and synthesis of a business model and similar tools.
3. Outside professionals will add a relevant perspective in the course.
4. Entrepreneurial intention of the students should be fostered.
5. The method should be oriented to action (student centered education) rather than to entrepreneurial theory.
6. The method should include the pre-foundation and the post-foundation analysis of an entrepreneurial idea.

Taking into account the previous 6 principles, the analysis of the actors that participate in the experience follows:

- The Students. MSc students, with a technical background and fundamental skills already developed during the Bachelor and during the previous courses.
- The Teacher. Specialised in the topic of the MSc programme and with experience in Entrepreneurship Education, both from the theoretical side and the performance side (knowledgeable about start-up cases).
- The Business Advisor. An outside professional that complements the knowledge by the Teacher, providing a deep contextualization about the business aspects.
- The Start-up. A real start-up participates in the assignment.

In summary, the assignment for the students is built around the analysis of the pre-foundation and the synthesis or development (post-foundation) of a real start-up. Everything working in a team and in collaboration with the teacher and the business advisor, in a professional way. The synthesis of the start-up case is elaborated by the students, with proposals about the start-up development. An interview of the students with the start-up CEO (or other C-level positions) is arranged in such a way that a consolidation of the case is made. A final elaboration of the start-up case is done by the students consolidating their findings after the interaction with the CEO during the interview. The assignment is described in the flow diagram of Figure 1.

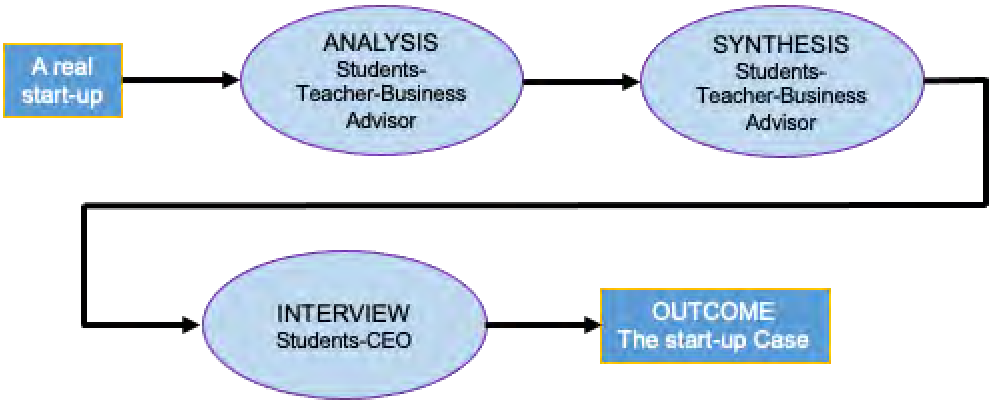

Fig. 1. Flow diagram of the assignment.

The explanation of the interactions among the actors is graphically shown in Figure 2. The teacher and the business advisor interact 3 times with the start-up: first, before starting the semester, for the global preparation of the assignment; second, for the preparation of the interview students-CEO and, third, for a post semester wrap up.

The students interact once per week with the business advisor and the teacher presenting their current work, with a later debate. The students interact additionally once per week with the teacher, for clearing technological concepts. The students have only one interaction with the start-up, for the interview with the CEO.

Finally, the teacher and the business advisor run mutual interactions before the semester (preparation), during the semester (execution) and after the semester (wrap up).

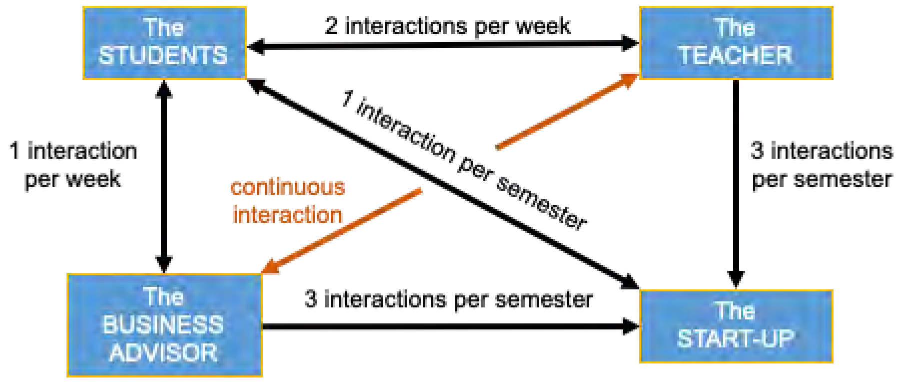

Fig. 2. The interactions among the actors in the assignment.

The content of the assignment is shown in a block diagram format in Figure 3.

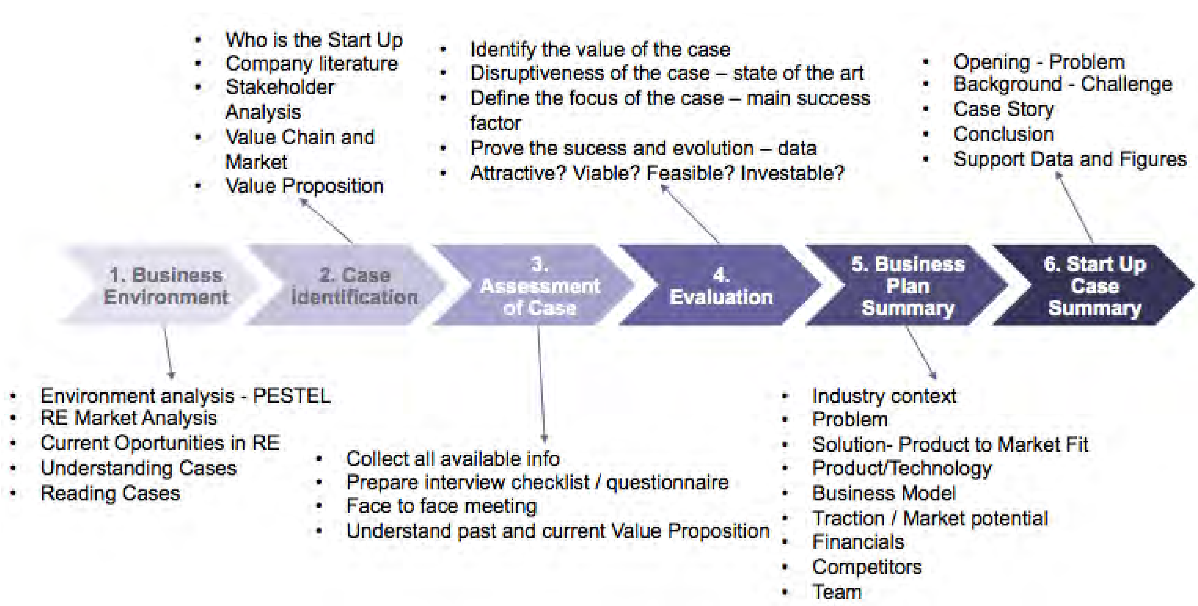

Fig. 3. Block diagram of the assignment content.

The block diagram shows the 6 steps for making feasible that all the objectives of the assignment are completed:

1. Business Environment: pre-development of the start-up, analysing the context.
2. Case Identification. This step is also part of the pre-development. The students work in detail on the value proposition of the start-up.
3. Assessment of Case. Progress in the analysis of the start-up and preparation of the interview with the CEO.

4. Evaluation. Completing the analysis of the start-up and running the interview with the CEO.
5. Business Plan Summary. After the interview with the CEO, the business plan of the start-up looks clear.
6. Case summary. Wrapping-up all the analysis and synthesis of the assignment.

The 6 steps along with the bullet points in Figure 3 constitute a checklist of all the points to be worked in the analysis.

2.2 Implementation

The method has been implemented in MSc RENE (Master`s in Renewable Energy), one of the programmes of the EIT InnoEnergy Master School. This programme is awarded with the EIT Label, under the quality seal of the EIT Quality Assurance and Learning Enhancement (EIT QALE). The University is UPC-BarcelonaTech, under the umbrella of the Master's degree in Energy Engineering, accredited in Spain by the Ministry of Education's degree register.

The course where the method is applied is "Renewable Energy Technology", a mandatory course in the semester 1 of the programme. This course is planned for a duration of 1 semester and a student load of 5 ECTS, equivalent to 125 hours of work per student. The method is implemented as the only assignment of the course for the student team. For making the load of the assignment proportional to the size of the course, a load of 25 hours per student has been chosen. Subsequently, the number of students in the team is designed to have a significant capacity to run the analysis and synthesis of the start-up case. The optimal number of students in the team is 4-6, since then an amount of 100-150 hours is available globally. The design of the method based in student teams shows different benefits:

- The amount of work available to generate significant results is matching the needs of the intended analysis.
- The work of the students in teams makes possible to improve the skills related with team building.
- Particularly, a number of even students in the team is preferred, since it forces the decision making by agreement instead of by voting, which is considered an additional benefit of the team building training.

The first week of the course, the business advisor and the teacher run a kick-off session, explaining how the assignment is organised and key topics about the analysis and synthesis of a start-up, such as success factors of start-ups, a short description of the start-up and some tools to analyse energy market scenarios.

From this point on, the student team runs the different phases of the process depicted in Figure 3 with the continuous mentoring of the teacher. One presentation per week is done by the student team.

The key moment during the assignment is the interview with the start-up CEO. The interview is led by the student team that has made a previous preparation with the business advisor and the teacher, who are also present during the interview.

The grading for 80% of the course is done by the teacher consulting the opinion of the business advisor. Every phase of the assignment is graded: weekly presentations, preparation of the CEO interview, CEO interview, case report. At the end of the course, a peer evaluation is done, asking all the students to grade their colleagues and themselves. This mark weighs 20 % of the final grade. This grading method is motivating in the sense that keeps the student team concentrated in performing very well with the start-up case assignment.

3 RESULTS

3.1 Assignments done so far

The teacher and the business advisor have collaborated with EIT InnoEnergy in identifying start-ups in their portfolio that are thematically interesting for the scope of the course where the assignment is done and also attractive for the students.

The attractiveness for the students has been chosen because of addressing an interesting technology in the field of renewable energy and because of having a high level of innovation (architectural innovation, disruptive innovation or radical innovation). See (Christensen 2013).

An initial pilot with only one company was held in the autumn semester of academic year 2021-22 with Flexidao. The interview was conducted with Joan Collell, CGO, and Emanuele Rossi, Innovation and Product Manager. Flexidao has invented a renewable energy monitoring software. Four students participated in this assignment.

After the success of the pilot, 3 more cases were run in the autumn semester of academic year 2022-23. The companies and the number of students were:

- BeePlanet, a second life for EV batteries in renewable energy facilities. Four students worked on this case. Jon Asin, CEO, participated in the interview.
- Ezzing, optimises the whole value chain of stakeholders in solar PV installations. Five students worked on this case. Víctor Sancho, CEO, and Blanca Cidoncha, Head of Business Development, participated in the interview.
- X1Wind, has patented and developed a disruptive floating wind system for offshore wind turbines. Four students worked on this case. Alex Raventós, CEO, participated in the interview.

3.2 Results of the student surveys

Globally, 17 students have participated in the 4 editions of the start-up case assignment. They are coming from 10 countries in 4 continents. This means a variety of perspectives in the class. Table 1 shows a summary of the answers in the student surveys, designed to assess if the new method to develop entrepreneurship education presented in this paper is valuable.

Qualitatively, the results show the high level of engagement of the students with the method: professional experience with the business advisor and the start-up CEO, acquiring knowledge contextualised with business, knowing the essentials to become entrepreneurs, practising soft skills in team building and communication. Definitely, the experience of the interview with the CEO shows the best results and it was additionally identified as the key element of the method when the students were informally asked in the lecture room if running the method without such an interview could be equally valuable. The answer was clear: definitely, not. This is the “positive adrenaline”.

Table 1. Summary of the student surveys answers

4 CONCLUSIONS AND ACKNOWLEDGMENTS

A new method to develop entrepreneurship education in a student centered approach has been presented. The method is valid for any course in an engineering master and also facilitates the development of soft skills by the students.

The combination of the work of the teacher and a business advisor has proven to be very effective to create a strong engagement with the student teams. The business advisor shows a relevant level of empowerment, because of the practical experience in developing businesses.

The idea of co-working the analysis and synthesis of a real start-up case among the student team, the teacher and the business advisor is certainly strong. And, very specially, the level of “positive adrenaline” created because of the milestone defined by the interview with the start-up CEO is really high. Quantitatively and qualitatively, the students agree on how differential and engaging this experience is (surveys in Table 1).

The duration of the assignment is 25 hours per student and the work in a team makes feasible to get relevant results and is positively assessed by the students.

The method has the potential to be extended as an assignment in many engineering courses: the key point is in collaborating with a business advisor and with a start-up. Certainly this is an external element to the teacher and may be a limitation for the applicability.

ABSTRACT

Technological innovations are impacting societies in manifold ways and can accelerate a transformation toward sustainability. To enable a sustainable transformation through engineering, engineers educated to create technological solutions for global challenges must be educated in sustainability principles as postulated under 'Education for Sustainable Development' (ESD) in the Agenda for Sustainable Development. In technological fields, the ecological, as well as the economical perspective of sustainability, are often addressed, but as recent research has highlighted, sustainability needs to be addressed holistically; this means including the social dimension to a greater degree and applying an intersectional understanding of gender and diversity throughout all spheres of sustainability. It is therefore imperative for engineering students to learn and understand where gender and diversity are necessary for sustainability, how diversity dimensions intersect, and which intersections are particularly relevant for novel technologies and societal development. Accordingly, this paper sketches an interdisciplinary approach for applying intersectional gender and diversity studies in the context of a sustainable transformation of engineering education. We draw on our experience of having educated engineers accordingly for a decade at the GDI (Gender and Diversity in Engineering) at RWTH Aachen University. Selected examples from our teaching practice are presented and six general maxims are deduced that can make engineering education more sustainability-oriented, inclusive, and diverse. As we will conclude, fostering innovative and inclusive engineering education needs interdisciplinary teams adhering to our proposed six maxims to accelerate a gender- and diversity-sensitive sustainable transformation.

1 INTRODUCTION

Considering complex global challenges such as sustainable development, engineering education should transgress its disciplinary boundaries together with its classical reductionist focus on mere technical problem-solving (Takala and Korhonen-Yrjänheikki 2019; Sigahi et al. 2023). Accordingly, such challenges call for a new type of interdisciplinary educated engineers (Van den Beemt et al. 2020) that can cope with complexities, ambiguities, or uncertainties (Takala and Korhonen-Yrjänheikki 2019; Sigahi et al. 2023).

This is in line with the United Nations stressing that engineering, as an essential factor influencing sustainability, should integrate a gender-sensitive perspective of diversity and inclusion to foster a sustainable development that goes beyond a mere focus on ecological and economic factors (United Nations 2021). Correspondingly, researchers, educators, and practitioners must be enabled to discover and deal with complex intersections between gender and engineering as well as gender and sustainability (Khalikova, Jin, and Chopra 2021). Further, this signifies the need for educational initiatives that foster the development of critically reflective and socially responsible engineers (Steuer-Dankert et al. 2019). While practically-oriented research on engineering education has suggested how intersectional gender and diversity studies can improve engineering education (Leicht-Scholten 2019), there is less research focusing on how to integrate the intersection between gender and sustainability in the context of engineering education.

Having applied intersectional gender studies along with a broad understanding of sustainability in engineering education for more than a decade at the Institute Gender and Diversity in Engineering (GDI) at RWTH Aachen University, in this paper, we contribute to closing this gap by proposing six maxims derived from literature and our practical experience to lay the foundation for future developments in sustainability education.

2 METHODOLOGY

As a starting point, we will outline selected research findings on the relationship between gender, engineering, and sustainability that are to be considered for a holistic education that acknowledges intersectionality as a connecting anchor between these topics. After this, we briefly present two exemplary educational approaches that already put these intersectional and holistic understandings into practice. We then deduce six generalized maxims on how to apply an intersectional sustainability perspective to engineering education.

3 THEORETICAL BACKGROUND: ENGINEERING EDUCATION AND THE INTERSECTION OF GENDER AND SUSTAINABILITY

As we highlighted in a previous paper on the contribution of gender research to engineering education (Leicht-Scholten 2019) and illustrated referencing our teaching concept of “Expanding Engineering Limits” (Steuer-Dankert et al. 2019) developed in cooperation with Stanford University, integrating a perspective of intersectional gender studies into engineering education fosters a form of critical reflexivity that allows students to understand sustainability holistically. To reach this, students must, in the first place, develop an understanding of the intersections of gender, understood as socially constructed roles, behaviors, and expectations, that are enacted based on culturally produced ideas of being male or female (Gildemeister 2010), and engineering. Students' development of holistic perspectives profits from learning about topics such as masculine-coded engineering cultures (Faulkner 2000), identities (Cech 2015), artifacts (Cockburn and Ormrod 1993), and processes (Male et al. 2018), that are prevalent in the context of engineering (Leicht-Scholten 2019) and that derive from the gendered culture of society in general (Carberry and Baker 2018). In doing so, students reflect on how these gendered realities generate privileges for white able-bodied heterosexual men in engineering cultures (Cech 2022). Accordingly, students discover that this not only leads to an exclusionary and often discriminatory educational and professional culture for female or other marginalized groups of engineers but also limits innovations that are needed to foster sustainable development of technology and society (Schiebinger et al. 2011-2020). To develop this kind of holistic understanding, students need a fundamental knowledge of the concept of *intersectionality* (Crenshaw 1991). This knowledge of intersectionality can be applied as a tool to recognize that different categories of social identities, such as race, gender, class, ability, and sexual orientation, intersect and create unique experiences of oppression and privilege (Crenshaw 1991) in the context of engineering (True-Funk et al. 2021) and sustainability (Khalikova, Jin, and Chopra 2021). With this at hand, students are enabled to apply a holistic understanding of sustainability that includes an intersectional understanding of gender and diversity, how gender and other intersecting identities (such as race, class, and sexual orientation) intersect with environmental sustainability, and how these intersections can be addressed comprehensively and effectively. This intersectional sustainability perspective acknowledges that people can experience multiple forms of oppression and discrimination simultaneously and that these intersecting experiences and identities must be considered when sustainability is the goal (Khalikova, Jin, and Chopra 2021).

Recent research has highlighted how gender and other factors intersect with sustainability. For example, women and other marginalized groups often bear a disproportionate burden of the negative impacts of environmental degradation and climate change, such as food insecurity, displacement, and health problems (Odrowaz-Coates 2021). Women are also often excluded from decision-making processes related to sustainability and conservation (Odrowaz-Coates 2021). Thinking of sustainability in terms of intersectionality requires acknowledging and addressing the interactions between societal inequalities and environmental degradation. This involves understanding that environmental problems, such as climate change and biodiversity loss, disproportionately affect marginalized communities, such as low-income communities and communities of color. At the same time, social justice issues, such as poverty, racism, and gender inequality, can also contribute to environmental degradation (Prati, Cazcarro, and Hazra 2022). Such interdependencies are also becoming increasingly relevant in the context of digital transformation and Artificial intelligence (AI), where intersections between sustainability (Van Wynsberghe 2021), gender, and diversity (Buolamwini and Gebru 2018), are discussed in the context of a sustainable transformation of society and technology.

To address such intersections successfully, an inclusive and holistic sustainability approach that considers the needs and perspectives of diverse stakeholders, including those from marginalized communities, is necessary. This includes recognizing and addressing the differential impacts of environmental degradation and climate change on different groups and incorporating equity and social justice considerations into sustainability policies, practices, and education. Further, it means developing more inclusive and participatory decision-making processes as well as promoting the participation of marginalized groups in decision-making processes (Khalikova, Jin, and Chopra 2021; Odrowaz-Coates 2021).

Consequently, such a holistic perspective should be incorporated into educative approaches to foster the development of responsible engineers that can identify, dissect, and improve complex intersections among engineering, sustainability, and gender, to reach a sustainable future as requested by the United Nations (United Nations 2021).

4 APPLYING GENDER, INTERSECTIONALITY, AND SUSTAINABILITY IN ENGINEERING EDUCATION

The GDI at RWTH Aachen University is unique in Germany in its positioning as a bridging professorship between the Faculty of Civil Engineering and the Faculty of Arts and Humanities (Trujillo et al. 2023). With the research group's experience of having educated engineers for more than a decade, the interdisciplinary team of scientists at the GDI under the leadership of a political scientist focused on Gender and Science and Technology Studies (Gender STS), are pioneers in educating engineering students at the intersection of gender, diversity, engineering, and sustainability (Leicht-Scholten 2019; Decker, Winkens, and Leicht-Scholten 2022).

To offer a practice-oriented perspective deriving from this experience, in the following, we present two examples of engineering education developed and implemented by the GDI.

4.1 Teaching the Fundamentals: Lecture "Engineering and Society"

As stated, engineering education that aims to create technological solutions for global challenges must follow principles of sustainability, as postulated under 'Education for Sustainable Development' (ESD) in the Agenda for Sustainable Development (United Nations 2023). Oftentimes, the idea of sustainability taught focuses strongly on environmental and ecological sustainability but neglects the perspective of social sustainability and intersectionality. However, if engineers are required to build sustainable solutions, they need the tools to understand social structures and communities and to reflect upon the impact of their work on society's environment (Bosen and Leicht-Scholten 2020; Walden et al. 2020). Therefore, engineers must be taught to critically reflect upon the intersectionality of factors of sustainability.

At larger technical universities in Germany engineering education most often includes teacher-centered lectures in front of hundreds of students with little to no active participation and reflection by the students. In contrast to this, the GDI lecture "Engineering and Society", which is a mandatory Bachelor's course attended each year by about 500 engineering students, utilizes participatory concepts of a flipped classroom and blended learning strategies. Through this, students learn about the importance of sustainability, (technology) ethics, and societal structures in their future engineering careers (Decker, Winkens, and Leicht-Scholten 2021). The course has been well-evaluated by students with an interest in the topics for its participatory and intersectional teaching approach to the topics of gender and diversity in connection with engineering and sustainability (Decker, Winkens, and Leicht-Scholten 2022).

4.2 Practicing Inclusion and Diversity in Engineering Education: BIOS

Engineering study courses often are challenging in the first years, with dropout rates among the highest of all courses of study and this disproportionately affects students from non-academic family backgrounds or with less social and cultural capital (Heublein et al. 2017). We propose that an intersectional understanding of sustainability should not just include what is taught but also who is taught. It is therefore imperative to make engineering education more inclusive and diverse.

For this reason, RWTH Aachen University and Aachen University of Applied Sciences jointly launched the cooperation project "A Good Start to Engineering Studies" in 2015. Building on the successful cooperation project, the independent cooperative study course "Civil Engineering with Orientation Semester" (German acronym: BIOS) was introduced in the summer semester of 2020 (GDI n.d.b).

The eight-semester Bachelor's degree course includes one extra semester, providing students with first-hand insights into the civil engineering courses at the two universities and helping them to decide which one fits best for them. Whereas one is a university of applied science with relatively small classes and a practical approach, the technical university of Aachen has larger cohorts, less direct interaction with teachers, and a strong research orientation. Being able to compare the teaching formats, facilitates an individual study decision for the type of university and engineering course for students. It aims to lower the barrier to studying at the university level, which could be particularly valuable for people with a migration background and "first-generation students" (GDI n.d.a).

Following the GDIs approach to teaching the fundamentals as early as possible, BIOS is one of only a few engineering degree programs in Germany that include a mandatory module on responsibly designed technology development.

5 RESULTS – THE GDI-APPROACH

Deriving from scientific literature and our practical experience, we now propose six maxims–that is, propositions generalized from our practical experience in combination with the theoretical state of the art–to follow to successfully apply interdisciplinary educational initiatives on the cross-section of intersectional gender studies, engineering, and sustainability:

1. Anchoring concepts firmly in disciplinary discourses and ensuring interdisciplinary iteration from the beginning–thereby ensuring theoretical integration with the existing disciplinary states of the art and developing new concepts that are more easily translatable into an interdisciplinary practice.

To be able to apply gender studies interdisciplinary, understand where diversity dimensions intersect, and which intersections are especially relevant for the given context, a fundamental understanding of the disciplinary, theoretical discourses on gender and diversity studies and social science methodology is necessary (cf. also Walden et al. 2020; Takala and Korhonen-Yrjänheikki 2019). However, conceptual frameworks only developed disciplinarily often come at the expense of interdisciplinary applicability. This is why we, following, amongst others Van den Beemt et al. (2020); Takala and Korhonen-Yrjänheikki (2019), propose that teams developing concepts to be applied interdisciplinarily should ideally be interdisciplinary from the start and include both disciplinary and scholarly expertise in gender and diversity studies as well as the sciences the concept is developed for. When teams that have fundamental knowledge in social sciences and gender and diversity studies as well as fundamental knowledge in engineering and natural sciences work together on the development and research of concepts, these concepts stand the challenges of interdisciplinary application. This is because interdisciplinary cooperation is already applied in the first sketches of the conceptual frameworks that are then developed further to be taught in interdisciplinary contexts, such as engineering education.

2. Translating disciplinary theoretical concepts into interdisciplinary contexts.

Through iteration in interdisciplinary teams, we translate the theoretical disciplinary state of the art into interdisciplinary contexts. For this, communication in an interdisciplinary team is essential. This is also where empirical data can be disciplinarily evaluated and interdisciplinary validated (cf. for example Bosen, Fuchte, and Leicht-Scholten 2023). This way, there is interdisciplinary communicative validation from the beginning of the conceptual development and even though concepts are still on a theoretical level at this stage, a first round of reviewing intersectionality is also provided, as stereotypes and disciplinary preconceptions are challenged. This step profits from diversity in the team, including as many diversity categories as possible.

3. Example-based communication of these translated concepts–thereby facilitating interdisciplinary understanding.

The theoretical concepts then need to be prepared to be communicated to teams from other disciplines and outside of academia. The challenge here is to not reduce the complexity of the concepts (Sigahi et al. 2023) because we have discovered that this does not lead to satisfactory results (Berg, Steuer-Dankert, and Leicht-Scholten, under review). To facilitate communication or teaching without having to dilute the theoretical concepts, we propose using examples that ideally come from the realm of the target group that is taught these concepts. This way, interdisciplinary compatibility is generated without compromising on the complexity of the taught concepts.

4. Case work–thereby facilitating interdisciplinary understanding and applying the concepts to the relevant interdisciplinary areas.

To illustrate the complexity of theoretical concepts and thereby make them more tangible (Sigahi et al. 2023) as well as to intensify this example-based communication of theoretical concepts, casework has proven a fruitful tool. Cases are examples that are given in greater detail and/or developed by the students themselves. They offer a concrete, multifaceted context for the theoretical concept to be applied by the students (Leicht-Scholten 2019). Students work over a longer period on these cases and develop and shape them. This way, they can shape the cases to their background, hands-on apply the theoretical disciplinary concepts interdisciplinarily, and, thereby, learn to deal with complexities, ambiguities, and uncertainties (also) outside their disciplinary boundaries (Takala and Korhonen-Yrjänheikki 2019; Van den Beemt et al. 2020).

5. Peer-group discussions–thereby encouraging individual reflection and facilitating a low-threshold exchange of the learned concepts in peer groups.

This might be combined with 3. Casework can also be executed as a separate step de-coupled from the casework. Students could be guided by guiding questions or design thinking methods (Leicht-Scholten and Steuer-Dankert 2020). Diversity and heterogeneity of peer groups are preferred and only minimal intervention by the teacher in the discussions at this stage is preferred.

6. Discussion and iteration – thereby re-iterating conceptual framework for new applications but also furthering state-of-the-art discussion in disciplinary contexts.

As a final step, it is imperative to encourage discussions across the peer groups and engage all students in a broader discussion but also to collect feedback so that lecturers may re-evaluate their concepts, starting again with phase 1.

6 DISCUSSION

We proposed a novel practical attempt to bring together research from intersectional gender and diversity studies and sustainability in the context of engineering education, acknowledging that engineering, and gender inclusion, play a crucial role in sustainable development (United Nations 2021; Khalikova, Jin, and Chopra 2021). While there have been attempts to better integrate the social dimension into sustainability discourses (Odrowaz-Coates 2021), there has been no interdisciplinary approach, rooted in both research and practice, that conceptualizes the interdependencies between intersectional gender and diversity studies and sustainability studies in the context of engineering education. Accordingly, our proposed maxims help fill this gap and thus align with the United Nations' call for "new approaches within higher education and, possibly, even a fundamental reconceptualization of teaching and learning" (United Nations 2017, 5) in the context of education on sustainable development.

Our proposed maxims are generic in their current form. While this might limit their scope, it allows for adaptability to different contexts and improvements after application in practice. Correspondingly, their generic outline offers flexibility and adaptability and, therefore, aligns with the demands of fostering reflectivity, creativity, and innovativeness within the development of engineering education (Takala and Korhonen-Yrjänheikki 2019). This becomes apparent in the maxims *4) case-relatedness*, *5) participation,* and *6) discussion or iteration,* since these phases promote, when combined, a reflexive and collaborative hands-on practice demanding and fostering students to develop social skills (Lopes et al. 2015; Bairaktarova and Pilotte 2020).

The maxims *1) anchoring*, *2) translating* and *3) exemplarity* correspond to the demand for inter- and transdisciplinarity in the context of sustainability science and education (United Nations 2017; Van den Beemt et al. 2020). Because they, as also proposed by Sigahi et al. (2023) and Takala and Korhonen-Yrjänheikki (2019), extend the classical disciplinary engineering focus on sustainability by introducing relevant and contextualized insights on an intersectional and interdepended perspective on sustainability, and thereby foster complexity-thinking in a broader sense. This challenges engineering students' tendencies to reduce given issues to, e.g., mere technical aspects (Sigahi et al. 2023) and, accordingly, assists their "develop[ment] from technical problem-solvers to collaborative creators capable of defining relevant questions, and creating solutions, to complex transdisciplinary problems" (Takala and Korhonen-Yrjänheikki 2019, 175f.), such as sustainable development.

Accordingly, the proposed maxims of *1) anchoring*, *2) translating*, *3) exemplarity*, *4) case-relatedness*, *5) participation*, and *6) discussion* or *iteration*, offer guidance to educate engineers on topics of gender and diversity studies and sustainability while contributing to transforming engineering education towards sustainability by assisting the development of interdisciplinary competencies, critical complexity-thinking, adaptability, as well as collaborative social skills.

7 CONCLUSION

To engineer a sustainable and just future, interdisciplinary educational initiatives are needed that use case-based and participatory learning approaches to convey the interdependencies and intersections of gender, engineering, and sustainability. This requires interdisciplinary teams that can develop innovative teaching and learning concepts based on our proposed maxims of *1) anchoring, 2) translating, 3) exemplarity, 4) case-relatedness, 5) participation, and 6) discussion or iteration* as well as further research on the introduced intersections between gender, engineering, and sustainability.

Conference Key Areas: *Curriculum Development, Innovative Teaching and Learning Methods*
Keywords: *Competency Framework, Curriculum Mapping, Constructive Alignment, Self Directed Learning, Flexible Study Paths*

ABSTRACT

Introduction – How to formulate the goals of an academic educational program in such a way that they reflect the identity of the profession, but at the same time allow the flexibility required for self-responsible and self-directed individual study paths that can initiate lifelong learning and successful interdisciplinary collaboration after graduation? Here, we present a novel competency framework that (1) reflects the identity and academic level of the interdisciplinary Biomedical Engineering (BME) profession, (2) permits the alignment of program intended learning outcomes that accommodate the content of the different specialisation tracks of the BME program and (3) guides students and staff by improved curriculum mapping and optimization.
Methods – We collected input from teaching staff members who are actively practicing their BME profession in the interdisciplinary ecosystem around our university. Using their feedback, we iteratively formulated a set of core competencies that characterize the work and role of the BME professional. We obtained preliminary face-validity by performing curriculum mappings from several courses from BME-

[1] *Corresponding Author (All in Arial, 10 pt, single space)*

J.R. Buitenweg

j.r.buitenweg@utwente.nl

tracks and by asking feedback from students. Results – The iterations resulted in the FIRIS-P competency framework including five successive core professional competencies of which specified subcompetencies carry the BME identity: (1) Fundamental competencies, (2) Instrumental competencies, (3) Reasoning competencies, (4) Interventional competencies, and (5) Societal competencies. These core professional competencies are completed and supported by transferable Personal competencies. Discussion: Preliminary validation indicates that the FIRIS-P framework carries all three characteristics mentioned above, warranting future evaluation of its merits for education of lifelong learning BME professionals.

1 INTRODUCTION

In our rapidly changing society, facing complex challenges, we need lifelong learning academic professionals who continuously adapt to new circumstances and who can collaborate and contribute in an interdisciplinary context. Our educational programs should respond to that need by providing our students from 'day one' with meaningful guidance and training to take control of their self-directed individual development pathway. A main challenge we face here, is to offer a continuously optimized and flexible educational content that enables our students to gain professional mass and direction on this pathway, but at the same time sufficiently preserves the identity of the profession to ensure the value of the diploma.

1.1 Local Context: Our Biomedical Engineering program

During the last decades, Biomedical Engineering (BME) has evolved from a collection of mono-disciplinary professions with their own specialization towards their application in the medical field, to a fully interdisciplinary profession in its own right. Our Biomedical Engineering educational master program includes four specialisation tracks that are aligned to the research domains of our TechMed institute:

- Biorobotics (BRB) – focusing on the use of mechatronic systems for improved surgical interventions or rehabilitation.
- Imaging and in-vitro diagnostics (IVD) – focusing on visualising the human body and detecting abnormalities in cells and tissues in order to detect diseases and monitor health.
- Physiological signals and Systems (PSS) – focusing on the observation and modulation of human body systems (e.g. sensory, motor and endocrine), which can be dysfunctional due to trauma or disease.
- Bioengineering Technologies (BET) – focusing on technologies that mimic or restore the function of diseased organs and damaged tissues, such as organs-on-chips or tumours-on-chips and targeted (nano)medicine.

As the Body of Knowledge and Skills (BoKS) differs largely between the tracks, each track has a tailored program content to prepare students for their final Masters assignment in one of the track related research groups. Our Techmed researchers – operating in the entrepreneurial ecosystem of our university - are also core teachers of many courses and actively participate in shaping the BME curriculum.

1.2 Problem statement and objectives

For the formulation of program goals and design of curricula, numerous competency frameworks have been developed, mostly to ensure that educational programs meet accreditation standards. Many frameworks show a clustering of (sub)competencies in competency areas or core-competencies, e.g. constructed from accreditation standards (Lu et al. 2019) or, the other way around, based on results from competence research (May and Terkowsky 2014) and subsequently validated using accreditation standards.

The Dutch accreditation system has adopted the Meijer's criteria for academic bachelor's and master's curricula (Meijers et al. 2005) as assessment criteria for the accreditation of engineering programs. These criteria are also formulated as a framework of competencies that university graduates should have at the start of their professional career (see textbox 1 for their clustering in core-competencies). In our Biomedical Engineering program we have aligned the final program goals to the Meijer's criteria. Although this approach supports guarding of the academic level of training within the program, the identity and core competencies of the BME profession are only implicitly reflected in the clustering and generic formulations of the Meijer's based competencies. This makes it more difficult to identify how available or required courses in the different specialization tracks contribute to the program goals, which in turn hampers both the optimization of the program content by staff and the targeted and flexible use of the program content by students. Not surprisingly, we observe that our program goals primarily play a prominent role in the accredication cycle of programs and are less actively used in curriculum design or for guiding self-directed learning by students.

Textbox 1: The Meijers Criteria for Academic Bachelor's and Master's Curricula [1]:
A university graduate
1. is competent in one or more scientific disciplines
2. is competent in doing research
3. is competent in designing
4. has a scientific approach
5. possesses basic intellectual skills
6. is competent in co-operating and communicating
7. takes account of the temporal and the social context.

On the other hand, (Degré and Castilo-Colaux 2016) argued that competency frameworks can be a powerful tool for academic staff to collaboratively design their courses as a coherent part of the curriculum, for students to be more involved in their education and to choose their studypath and for the dialog with the professional field. Indeed, if we expect students to prepare for self-directed lifelong learning by deriving a BME-specific dot on their horizon and by determining their own study path, we need clearly formulated program intended learning outcomes that (1) are aligned with an instructive competency framework that explicitly reflects the identity of the BME profession well beyond graduation, instead of focusing on entry competencies, and (2) can accommodate the BoKS and content of courses in the different specialisation tracks of the BME program in a straightforward way. In our opinion, to fulfill the cohesive, instructive and communicative roles as proposed by Degré and Castilo-Colaux, a competency framework should not only adequately accommodate the 'what' of all competencies, but also should feature a clustering into competency areas that coherently reflects the ‘how’ of successful academic professional contributions to society: It should facilitate teachers to share the narratives of the successes (and failures) in their professional practices and shape both the content and the pedagogical approach in their education. It should also facilitate students to recognize the combined functionality of these core competences in the work of professionals (inside and outside academia), to choose role models and to develop the narrative of their own career. In our experience, the Meijers criteria and many other competency frameworks insufficiently fulfill this requirement, which made us initiate the development of a framework with a more functional clustering.

2 METHODOLOGY

2.1 Formulation of the competency framework

We collected input from teaching staff members who are actively practicing their BME profession in the interdisciplinary ecosystem around our university. We took the consensus on our mission as biomedical engineers, as posted on our educational website at that time (textbox 2) as a starting point and we reflected on how we as biomedical engineers use fundamental scientific knowledge to develop technology and apply this technology to create products that solve healthcare problems. By focussing on the activities (verbs) mentioned in the mission statement and connecting these to the content of our very different biomedical engineering practices, we then discussed how we could use this narrative to present the BME identity more explicitly and instructively in a clustering of competencies that can comprehensively accommodate the content of the BME specialisation tracks.

Textbox 2: Our BME mission statement

Biomedical Engineering is an interdisciplinary field, combining engineering disciplines and natural and life sciences. By integrating scientific and engineering concepts and methodology the Biomedical Engineer works to increase scientific knowledge and solve health care problems, by:
1) acquiring new knowledge of living systems through continuous innovation and substantive application of experimental, analytical, and design techniques.
2) design and development of new devices, algorithms, processes and systems to advance Medical Technology in health care.
3) solving health care problems through purposeful context-driven problem solving;
4) implementing solutions using excellent cross-disciplinary communication and collaboration.

2.2 Program intended learning outcomes and curriculum mapping

We tested if the new competency framework permits alignment of program goals that clearly describe the abilities of the student at graduation, in terms of the content of the BME specialisation tracks. At each component of the framework, we formulated track specific intended learning outcomes (TILOs) for each track. Subsequently, we tested if the new framework permits mapping of the content of courses in the BME program offer to the components of the framework.

2.3 Student responses

To get a first impression of the instructional value of the new competency framework and the merits for self-directed learning, the competency framework was provided and explained to students (N=60: 12 BET, 13 PSS, 12 IVD, 23 BRB) of the compulsory MSc-BME startercourse ‘Technology for Health’. Subsequenly, the students were asked to recognize these competences in the work of TechMed researchers. As an individual assignment, each student was asked to report the result of self-reflection, based on the following questions:

- Expertise: Which of the BME subcompetencies do you like or consider as one of your strengths? Answer options: Strong, somewhat, not my expertise.
- Ambition: Which of the BME subcompetencies do you want to acquire before you graduate? Answer options: Need this, done this, not for me.
- Importance: Which of the BME subcompetencies are important in the professional field you envision yourself working? Answer options: Important, moderately important, not important.
- Program offer: Which of the BME subcompetencies are in your opinion poorly or not represented in your educational program or courses offered at our university? Answer options: Need more, sufficient, too much.

Besides obtaining these nominal reponses, students were asked to briefly motivate their ratings or provide examples (data not reported here).

3 RESULTS

3.1 The FIRIS-P Competency framework

Our reflective discussions and iterations resulted in the FIRIS-P competency framework including five interconnected core academic professional competencies of which specified subcompetencies carry the BME identity (see also Fig. 1). Subsequently, these core professional competencies were completed by adding transferable Personal competencies. Also an explanation to students was formulated (not presented here).

3.2 Program intended learning outcomes and curriculum mapping

In Fig. 2, the use of FIRIS-P for program intented learning outcomes and curriculum mapping is depicted. For all subcompetencies, track specific intended learning outcomes (TILOs) can be formulated that specify the BoKS that should be mastered at graduation. By formulating different TILOs for different specialization tracks (see Textbox 3 for an example), the contribution of track content to the BME identity carrying competencies can be specified, despite differences between the tracks. Subsequently, the mapping of (desired) course content contributing to the attainment of TILOs becomes straightforward.

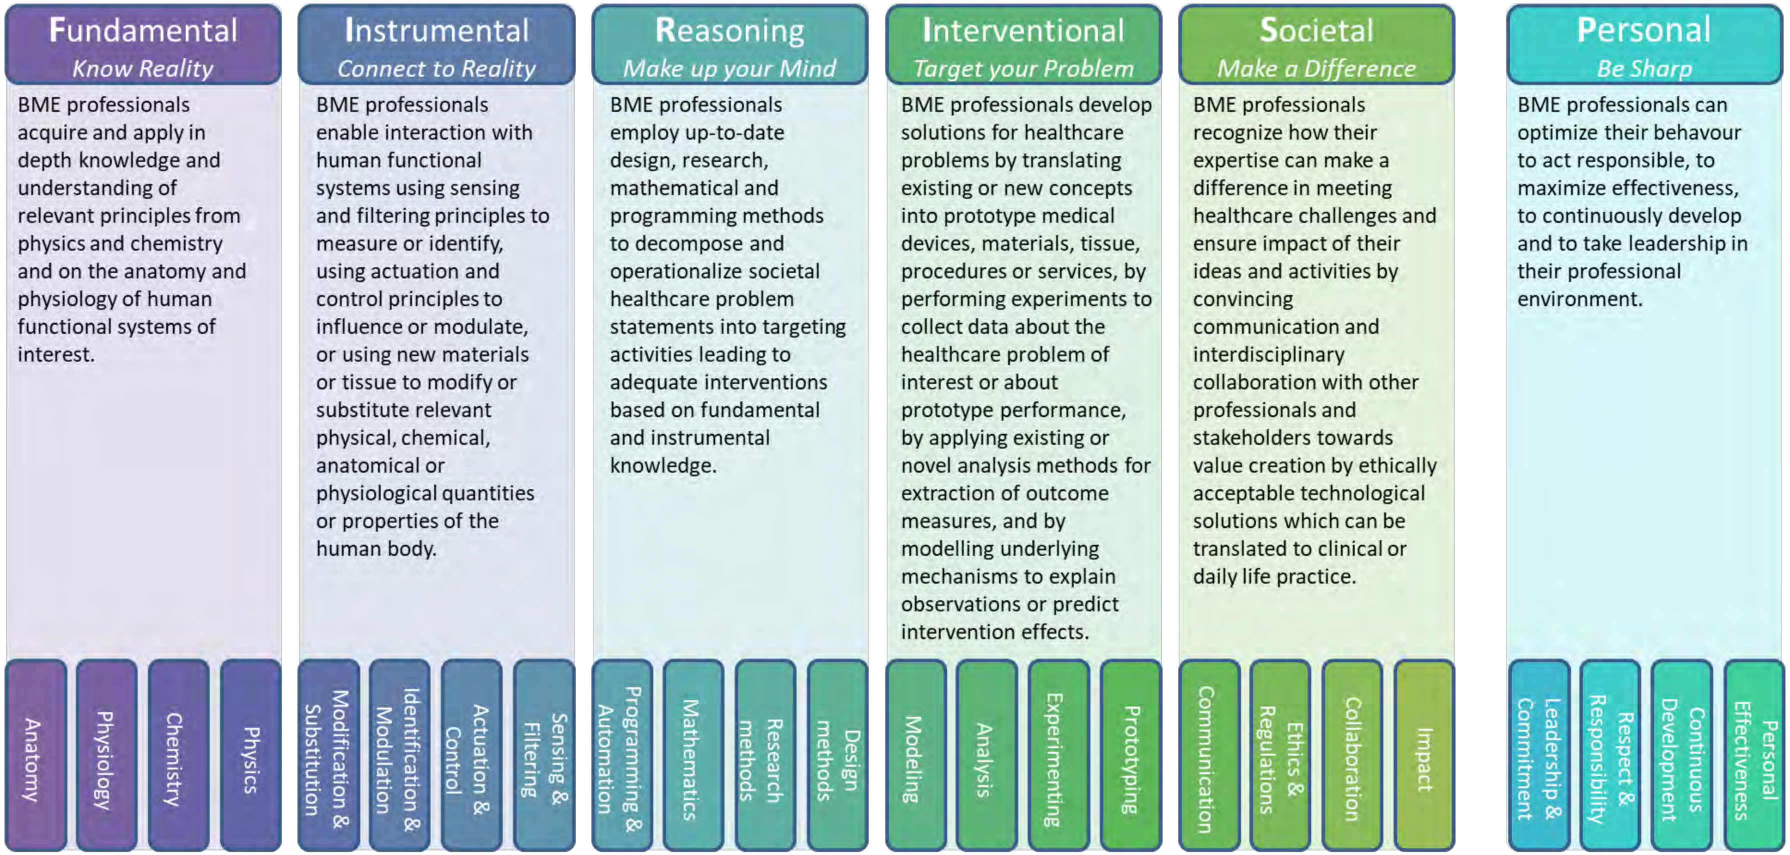

Fig. 1. The FIRIS-P competency framework, in which the identity of the BME profession is made explicit in five core professional competencies (FIRIS), representing the way engineers impact society by interventional activities in which they thoughtfully employ fundamental and instrumental knowledge and skills. At each core competency, BME specific subcompetencies are formulated, linking the BME identity to relevant BoKS content. The FIRIS part is completed by Personal competencies, describing transferable knowledge, skills and attitudes needed for sustained effectiveness as a professional.

Textbox 3: Example of track specific program intended learning outcomes, connecting concrete BoKS to the FIRIS-P subcompetency Sensing & Filtering (Instrumental competencies)
Biorobotics - The student can employ physical and chemical principles to obtain analog and digital signals which are sensitive to relevant quantities of human body and/or robotic systems of interest and can employ analog and digital signal processing methods to increase the specificity of these signals towards the human and robotic system behavior of interest.
Physiological signals and systems - The student can employ physical and chemical principles to obtain analog and digital signals which are sensitive to relevant quantities of human body systems of interest and can employ analog and digital signal processing methods to increase the specificity of these signals towards the human system behavior of interest.
Bioengineering technologies - The student can employ biophysical, optical and molecular biological techniques to study the function of human cells and tissues in healthy and diseased states.
Imaging and in-vitro diagnostics - The student can employ physical and chemical principles to obtain spatiotemporal signals which are sensitive to relevant changes in human anatomy of interest and can employ analog and digital signal processing methods to visualize these signals and increase their specificity towards specific disease progression.

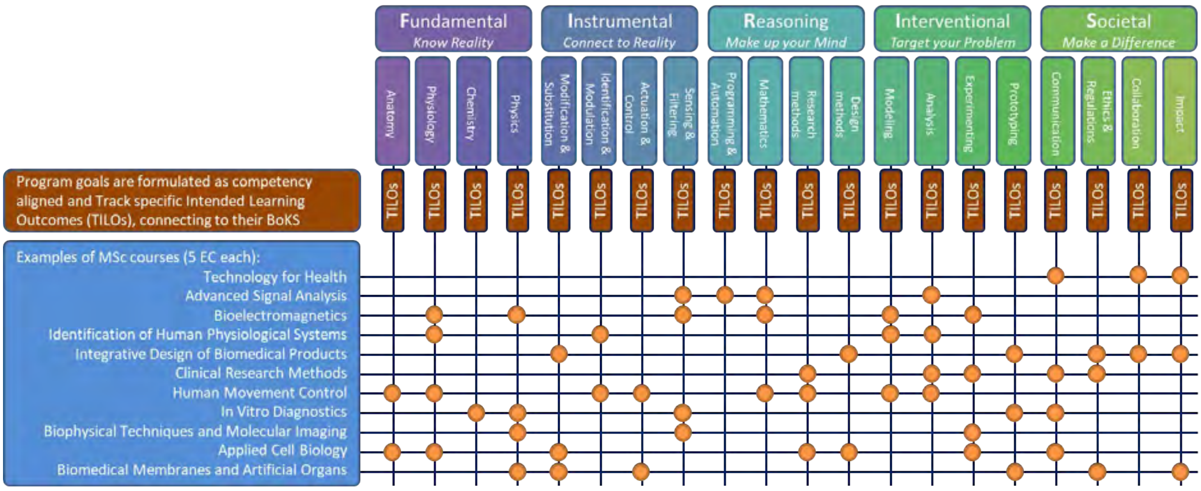

Fig. 2 The connection between the FIRIS-P framework and the BME BoKS can be realized through the formulation of Track specific program Intended Learning outcomes (TILOs, see textbox 3 for examples). To illustrate curriculum mapping, contributions from several courses from the BME program offer to the FIRIS-P aligned TILOs are depicted.

Meijer's Criteria FIRIS-P	Fundamental	Instrumental	Reasoning	Interventional	Societal	Personal
1. Is competent in one or more scientific disciplines	☑	☑	☑	☑	☑	
2. Is competent in doing research			☑	☑		
3. Is competent in designing			☑	☑		
4. Has a scientific approach	☑	☑	☑	☑		
5. Possesses basic intellectual skills			☑	☑	☑	☑
6. Is competent in co-operating and communicating					☑	☑
7. Takes account of the temporal and the social context					☑	☑

Fig. 3 Preliminary mapping the FIRIS-P competency framework on the Meijer's criteria.

3.3 Accreditation aspects

Of course, also with FIRIS-P aligned program intended learning outcomes our BME program should still meet the accreditation criteria, in our case the Meijer's criteria. In Fig. 3 is depicted how FIRIS-P core-competencies (preliminary mapping only, subcompetencies omitted for brevity) contribute to meeting the Meijer's criteria. All Meijer's criteria are covered by multiple FIRIS-P competencies, showing where these criteria are relevant in the BME profession.

3.4 Student's response

After explanation of the FIRIS-P framework and practicing with recognizing the competencies in the work of TechMed researchers, the students reported their self-reflections on each subcompetency of the FIRIS-P framework (see Fig. 4). Most students reported strong or moderate expertise on all subcompetences, as obtained during their preceeding BSc program. Some students reported subcompetencies on which they rated their expertise as (almost) 'none'. Similarly, the students reported varying ambitions to learn more and estimated importance of subcompetences for their future professional practice. Finally, the students reported the offered program content on each subcompetency as overall 'sufficient', but also expressed their need for more elaborate offer, e.g. on programming & automation and prototyping. It should be noted that the students reports may depend on the track they are following (not analysed here): For example, fundamental knowledge of chemistry is less prominent in tracks other than Bioengineering technologies (12 students), which might explain the reported lack of expertise, ambition and importance.

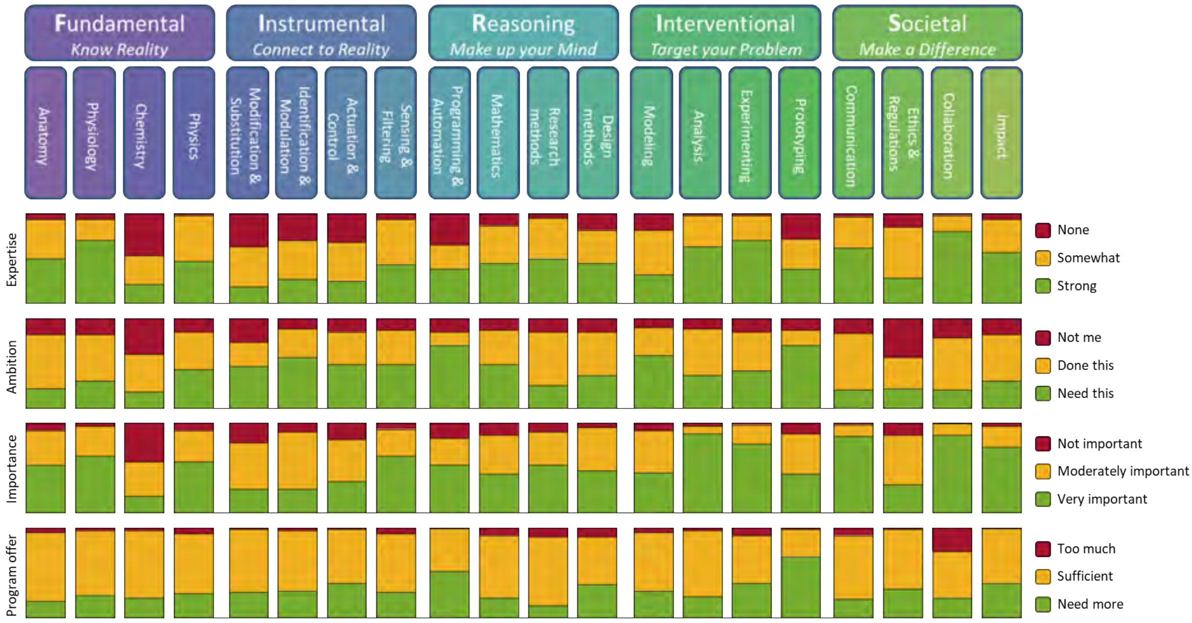

Fig. 4 Student self-reflections using the FIRIS subcompetencies. For each subcompetency, 60 MSc-BME students reported their level of expertise, their ambition to learn more, the estimated importance in their future professional practice and the learning opportunities offered by the program or at our university.

4 DISCUSSION

We aimed to formulate a novel competency framework that (1) reflects the identity and academic level of the interdisciplinary Biomedical Engineering (BME) profession, (2) permits the alignment of program intended learning outcomes that accommodate the content of the different specialisation tracks of the BME program and (3) guides students and staff by improved curriculum mapping and optimization. The resulting FIRIS-P framework and the preliminary validation we present here is stil work in progress, but can be of interest beyond the BME program for which FIRIS-P was developed.

4.1 Methodological aspects

We should note that the FIRIS-P framework is formulated in a local reflective process at our university. A direct benefit of this approach is the ownership of the formulations that arises with the staff contributing to the process, which enhances the teaching of FIRIS-P to students and – practice what you preach – supports being a role-model. Although the involved staff consists of active BME researchers operating in the entrepreneurial ecosystem of our university, the risk of being biased towards the content and identity of the BME professional practice cannot be fully excluded. Hence, it is recommended to validate and refine the FIRIS-P framework also with stakeholders from outside our direct ecosystem and the wider educational community. The initial validation steps we performed show some face validity concerning the connection to the BoKS of specialisation tracks, straightforward curriculum mapping and fulfilment of accreditation criteria. Furthermore a first impression of the instructional and guiding value of FIRIS-P for self-directed learning of students was obtained. As most of our students enter the Master BME after their BSc BME in our institute, many of them have made an informed choice for a specific specialization track during their 3rd year of the BSc program. This provides some level of understanding (e.g. Bloom’s: apply, SOLO: multistructural) needed for making FIRIS-P based formulations of their learning ambitions and matching these to the program offer. However, this level of understanding should be (and is, in the Technology for Health course) monitored and further increased by active engagement of the students and coaching by teachers and study advisors.

4.2 Merits of the FIRIS-P framework

In our view, a main improvement we reached with the FIRIS-P framework is the more role based clustering of competencies, i.e. a clustering that that more narratively reflects the way in which scientific and technological insights are employed for the benefit of society and that invites students to develop their personal professional narrative during their educational program and future lifelong learning career. The five-plus-one clustering of the FIRIS-P framework is likely to also allow formulation of the ‘professional narrative’ for other engineering, and perhaps even non-engineering academic programs: all (engineering) professions employ their fundamental knowledge and understanding of reality and instruments in reasoned way for impactful targeting of societal needs. If this is indeed the case, this might indicate that active awareness of the FIRIS-P structure might provide students and professionals with a cognitive structure that fosters interdisciplinary collaboration by providing students with a cognitive structure that facilitates the identification of their own disciplinary strengths using the FIRIS-P subtitles (see fig. 1) to find 'common grounds' with other disciplines (see also Claus and Wiese 2019).

***Conference Key Areas**: other topics in Engineering Education*
***Keywords**: didactic teacher qualification, evaluation, program design*

Empowering teachers for facilitating modern engineering education is essential. Thus, universities put much effort in qualifying teachers in didactic training programs. Especially individualized programs have been positively evaluated in the Covid-19-year 2020 by participated teachers. However, participants missed (informal) networking opportunities. Two questions arise: How do participants perceive their qualification program in the coming years? And second, how can we design a program that balances the participants' thirst for an individual program compilation while establishing university-wide networking opportunities among teachers? This paper presents participants' perceptions on a qualification program at a German University of Technology for the years 2021 – 2022. Also, it presents key practices of a revised program. After four groups completed their program, data was gathered through online questionnaires and descriptive analyses (48 responses of 106 participants). Also, four semi-structured interviews were conducted and content analysis was used as interpretation method. Results show that this qualification program is positively perceived in terms of acceptance, learning, future teaching activities and program characteristics. Specifically, participants define their training group as trustful, but only a part of them feel to share responsibility for teaching. Their personal teaching networks consists mainly of staff from the same school within the faculty and other mid-level academics. Interestingly, they encourage to tackle teaching challenges within the wider university community. Thus, both individual pathways and informal, cross-disciplinary opportunities for dialogue should be possible in a program that is flexible in terms of time and topics. Hence, qualification programs should be designed to address the challenges of contemporary higher education as a teaching community rather than as individual.

1 INTRODUCTION

Empowering teachers to enable modern pedagogy in engineering education is key in order to keep quality of teaching at a consistently high level while dealing with abrupt teaching transitions due to Covid-19 earlier (e.g. Sherman et al. 2023) or recently the enormous rise of artificial intelligence tools in teaching and learning (e.g. EUA 2023). Accordingly, associations and universities put much effort in qualifying teachers with didactic videos, podcasts, online or on-campus short formats, one-day workshops or complete training programs with varying approaches and workloads (e.g. E-teaching.org 2020, ECIU 2022, KI Campus 2023). Both, didactic qualification programs using cohort approaches according to Bulmann et al. (2018) and individual approaches have been positively evaluated as described by Bulmann and Bornhöft (2021). In the latter example that deals with the Covid-19-year 2020, participants found it more important to flexibly design their own program than go through a predetermined program in a cohort. However, they missed out on networking opportunities. Therefore, they recommended offering voluntary, primarily informal networking opportunities. Two main questions however remained and are pursued in this paper: First, how do participants perceive their flexible qualification program in the following years and how do participants describe their teaching networks. Second, how can we redesign the program so that the participants' thirst for individual program compilation and university-wide networking opportunities among teachers are balanced. This paper starts with describing the qualification program and the evaluation methodology. Results of participants' perceptions on the qualification program of a German University of Technology in the years 2021- 2022 are described. Based on these evaluation results and also taking reflections of didactic program experts into account, key practices of a revised program design are presented. This paper concludes on how to offer both an individual path as well as informal, cross-disciplinary options for dialogue in a didactic qualification program, striving for high quality, contemporary, transitioning engineering education.

2 METHODOLOGY

2.1 Implementing the Flexible Program

To ensure a high quality, contemporary education for mid-level academics, the executive committee of a German University of Technology initiated a flexible didactic qualification program, focusing on research assistants with teaching obligations. Attendance is obligatory for those funded by university budget. The program consists of 60-time hours over a maximum duration of two years. The aim is to enable participants to discuss didactic principles, apply methods and media to their teaching, develop their own teaching personality, present teaching-related products, and network across schools and faculties in terms of teaching. The program consists of an individual initial conversation (1 h), a variety of workshops (24 h), complementary elements (teaching project (21 h), peer visit (9 h), reflection (3 h)) and a final event for presenting the teaching project to the university public (2 h). Digital Teaching and Learning is a cross-cutting theme and reflects even more the adaptation of the training to Covid-19-disruptions in teaching and learning. Two main themes are offered, reflecting both the interest of previous participants and the identity and purpose of the university:

- “Higher Education and Engineering Pedagogy” (HE/EP) based on e.g. Berger et al. (2006) as well as
- “Engaging students in research with Research-Based Learning” (RBL) based on Healey (2005).

The broad area of HE/EP offers a wide range of didactic workshops in the catalog, while special RBL workshops have been offered continuously on two topics and additionally on varying topics. In the teaching project, participants innovate courses, analyze student learning or communicate about their teaching. In the peer visits, pairs of participants give each other feedback on their teaching in each other’s courses. In the reflection, participants review their teaching philosophy and practice. Every six months, a new group of participants begins and a previous group graduates from the program. Meanwhile, participants choose their own program path in regard to time and topics, based on their interests and needs for their current teaching practice and/or personal development. Flexibility, individualized pathways, and teaching practice based on a scientific foundation have been key features of the program since its inception. Four didactic experts guide the participants.

From the start of the program in 2019 to 2022, the program was constantly evaluated and iterated, based on the feedback of the participants and the reflection of the didactic experts. The program changes that were implemented foremost in summer 2021 include: (1) going back to on-campus workshops, (2) offering networking meetings in the reflection element, (3) shifting to the university learning management system, (4) suggesting to conduct peer visits with the teaching project partner, (5) recommending an optimal program duration of one year as well as (6) optimizing and digitalizing management processes to run the program.

The first group (G1) graduated in winter 2020/21, as described by Bulmann and Bornhöft (2021). From summer 2021 to winter 2022, 106 participants graduated in four groups (G2-G5). 55 participants were awarded with the certificate on the wide area HE/EP, while 51 participants received the special RBL certificate. 57 teaching projects have been carried out: 7 participants carried out their projects alone, 25 completed a project with a partner from the same school within the faculty, 10 with a partner from another school in the faculty and 15 even with a partner from different faculty.

2.2 Evaluating the Flexible Program and Deriving a Revised Program

We asked participants how they rated the qualification program after the first run and how they describe their teaching networks. We focused on the perceptions of four groups after they completed their programs: G2 (summer 2021), G3 (winter 2021/22), G4 (summer 2022), G5 (winter 2022/23). A mixed-method approach was applied: Data were collected from the four groups using self-administered online questionnaires and descriptive analyses (48 responses from 106 participants). In addition, four semi-structured interviews were conducted with participants of group 2 (summer 2021), of which two individuals completed the wide area HE/EP and two individuals completed the special area RBL. The interview guide focused on the overall evaluation of the program and the description of networks. The interviews were transcribed, coded, and interpreted using qualitative content analysis. Across the groups, the study was designed according to the first three levels of training program evaluation by Kirckpatrick and Kirckpatrick (2015): *Reaction* (R), *Learning* (L) and *Behavior* (B), while the latter refers to participants' future teaching intentions. Additionally, perceptions on teaching-related networks have been addressed: First, groups of persons that participants considered important in overcoming teaching challenges have been roughly identified. Second, personal networking maps with three levels of importance were used and interpreted according to Jenert (2021). And third, microcultures have been investigated according to the four types of microcultures by Roxa and Martensson (2015): *The Commons* with high trust and high shared responsibility ('We are in this together'), *The Club* with high trust and low shared responsibility ('We'll always support each other'), *The Market* with low trust and high shared responsibility ('I look after myself') and *The Square* with low trust and low shared responsibility ('Who are these people?'). Results on program evaluation (section 3.1) rely on questionnaires of four groups of graduates (i.e. G2 to G5), while results on networking (section 3.2) are presented based on interview data (of G2) and survey data (of G4, G5). The training program was then revised based on the evaluation results, reflections by didactic experts on running the training, emphasizing recent needs in regard to university strategies and contemporary engineering education.

3 RESULTS

3.1 Evaluation of the Flexible Program

Participants' Reaction, Learning, and Behavior Regarding the Program

Participants of all four groups (G2-G5) perceived the flexible qualification program as positive according to the questionnaire results (see Table 1).

Table 1 Participants' perception of a qualification program aggregated for four groups graduated in 2021 and 2022.

Level	#	Item	Ø	n
R	1	I find a structured didactic qualification as research assistant important.	1,4	48
	2	I find it personally valuable that I have participated in the program.	1,8	48
L	3	I can develop initial approaches for an aligned course.	1,5	48
	4	I can develop initial approaches for a research-based learning course.	1,6	23
	5	I can develop initial approaches for a digital course.	1,5	47
B	6	I am motivated to develop my own teaching continuously.	1,3	48
With three levels: Reaction (R), Learning (L), Behavior (B), answers on a 4-point scale with 1…totally agree to 4…totally disagree, Ø: arithmetic mean and n: number of responses from groups 2 to 5				

Participants' Perceptions on Individual Program Selection and Cohort Aspects within the Program

Participants rated the program positively in regard to the implementation of the four program characteristics: content flexibility (Ø=1.6, n=48), time flexibility (Ø=1.5, n=48), participants' needs (Ø=1.8, n=48), and teaching practice (Ø=1.8, n=48). In particular, participants find it more important to flexibly design their own program than go through a predetermined program in a cohort, i.e. 36 of 48 respondents voted for an individual design. So, the possibility to select workshops individually (groups 2-5: Ø=1.1, n=48) as well as to choose the focus of the complementary elements (reflection, peer visit and teaching project) (groups 2-5: Ø=1.5, n=48) was highly appreciated. In conclusion, participants appreciate the program's focus on their teaching needs and practice, and the opportunity to make their own decisions about their individual program pathways.

Participants' Perceptions of Program Support when it Comes to Solving Teaching Challenges

Participants experienced multidimensional challenges in Covid-19-times, especially related to organizing, designing, interacting, and assessing student learning in online teaching (despite group 5). Various program elements have been appraised as supportive to overcome these challenges (groups 2, 3): Impulses on digital teaching, such as didactic methods, techniques, tips, examples, the self-reflection element, peer visit element as well as exchange with other program participants, colleagues from other schools and didactic experts. Participants from group 4 (Ø=2.1, n=12) and group 5 (Ø=1.9, n=7) rated the support of the program as rather important.

3.2 Participants' Characterization of Personal Teaching Networks

Participants' Description of other Groups when it Comes to Solving Teaching Challenges (in Covid-19 Times)

Participants found it most important to overcome teaching challenges during Covid-19 times with colleagues of their own school and alone, followed by the university teaching community, didactic experts and colleagues of other schools (see Table 2).

Table 2: Participants perception of importance of others in overcoming teaching challenges

#	Item: "In COVID-19 times, how important is it to you to be able to master challenges with …?"	Ø	n
11	... colleagues of your own school?	1,2	48
12	... colleagues of other schools?	2,3	47
13	... didactic experts?	2,1	47
14	... the university teaching community?	1,9	47
15	... by myself?	1,4	47
Answers possible on a 4-point scale with 1…totally agree to 4…totally disagree, Ø: arithmetic mean and n: number of responses from groups 2 to 5			

Participants' Personal Networks for Teaching Exchange

The four interviewees (of G2) described their personal networks differently. Overall, they indicate that colleagues of the same school and other mid-level academics as well as professors, students, tutors, the program project partner and didactic experts are very important or important in their personal teaching network. Other groups, such as the IT department, the university's executive committee, industry colleagues, or previous colleagues are rated as a bit important (data not shown). This impression also correlates with the survey responses (of G4, G5) (see Table 3).

Table 3: Participants' perception of importance of other people for exchange on teaching

#	Item: "Who do you communicate with regarding your teaching, and how important are these people to you personally regarding your teaching?"	Ø	n
16	Colleagues from the qualification program	3,1	21

17	Colleagues from the same school	1,2	21
18	Colleagues from other schools/ faculties	2,8	21
19	Colleagues from other universities in your discipline (e.g. other universities; city/ national/ international)	3,4	20
20	Didactic experts of the Center of Teaching and Learning	2,4	21
21	Administrative staff (e.g. examination department, student administration office, IT department, library or others)	3,0	20
22	Colleagues on other academic levels (e.g. professors, senior researchers/ lecturers, tutors)	1,7	21
23	other persons (e.g. friends, family, industry/ business)	2,7	21
Answers were possible on a 4-point scale with 1…totally agree to 4…totally disagree, Ø: arithmetic mean and n: number of responses from groups 4 and 5			

Participants' description of Networks within their Schools and the Program regarding Trust and Shared Responsibility

The four interviewees (IA, IB, IC, ID) of group 2 explained in which way they share teaching obligations within their schools (professors/ head of school, senior researchers, colleagues of mid-level academics, tutors) and how they feel supported by didactic experts and the project partner. Microcultures within the schools and the program are described in the following:

First, the four interviewees positioned their teaching networks at their own school within three types of microcultures according Roxa and Martensson: 'The Commons', 'The Club' and 'The Market'. The fourth item 'The Square' was not chosen:

> *"Personally, I think is this, 'we are in this together.' But of course, it doesn't work like that* […] *So I would take either 'The Club' or 'The Market."* (IA, L410-118).
>
> *"So, in any case 'The Commons' […] always trust on* [person XY] […] *So much what sharing concerns."* (IB, L485-493)
>
> *"We are responsible together."* (IC, L230-234), *Rather 'The Commons' than 'The Market'*
>
> *"Between 'The Commons' and 'The Club'. The professor gives me a lot of trust and I give a lot of trust to the tutors, but the levels of responsibility are different. It's somewhat hierarchical."* (ID, L264-273)

Second, interviews (G2) and survey results of G4-5 outline that participants experienced the microculture within the program group predominantly within the three types: 'The Commons', 'The Club' and 'The Square', while 'The Market' was addressed only once. The digital format of the program was seen as hindering towards a feeling in the training group of 'We are in this together." (in G2 & G5). In particular, the working culture with the project partner (within or beyond the same school) was highlighted as being trustful and sharing ('The Commons'):

> *„I think that's where the digital teaching was a bit of a hindrance. That you just didn't have the feeling that 'we are in this together' or 'we will support each other'. But when I think about the project now. There I would even say that that was actually 'The Commons'. That we took this on together and supported it."* (IA, L422-427) ",*"The exchange with someone who is not in the school* [i.e. project partner], *who is already on the teaching side, but is not in his own school bubble, that really helped me. It substantially improved my teaching, simply because it was a completely different perspective. We understood each other well. It was a really good exchange."* (IA, L104-110)

“The Commons […] *the two participants, with whom I did the project* […] *they supported me relatively well.* […] *Otherwise, yes. I would say ‘What are you doing right now?’ somehow so ‘The Market’ or ‘The Club’.”* (IB, L499-517)

“More like ‘The Club’. We are a community of interest and want to make teaching better. But in the end, we do most of it on our own and in parallel and in independent groups. Even if a course goes over several schools, they are divided into several independent packages.” (IC, L237-240)

“Already so more ‘The Commons’. So, we have always acted as equals, especially in the workshops […]*. That things stay between us when it comes to a course, that you can tell each other things in confidence. We are in this together and go through it together and support each other in the things that are important to us.” (ID, L282-286). “Because it* [the program] *was digital, the exchange fell asleep. I only had exchanges with my project partner, otherwise we saw each other at the classroom events and we no longer had these discussions in breaks. That was difficult. That wasn't because of the program, but rather because of the* [Covid-19] *situation. The interpersonal level is very important to me, and it is precisely these discussions during breaks that lead to a more intensive exchange about things that are in teaching and things that are in everyday professional life. It's not just about what happens in teaching, but also what happens in research, and if all that falls away, there is less of a bond.”* (ID, L115-124)

These results outline the complexity of personal teaching networks. Both, while organically growing networks within the schools are of significant importance, trustful and sharing networks to project partners beyond the schools turned out to be essential for some participants. Both can be enforced within an on-campus program.

3.3 Our ten key practices of the revised qualification program

Our ten key practices of a balanced qualification program are presented here: Some practices (#4, 5, 8, 10) have been already introduced in summer 2021 (see section 2.2) and are feedbacked by some participants of G4 and G5 (see section 3.1., 3.2.). All practices are reflected in the recently published program (ZLL, 2023).

Practice 1: *Individual pathways*: Our training offers individual pathways along personal goals for newcomers, advanced and scholarly teachers. These are set in the initial talk by each participant. This aims that participants with all kind of interest, didactic backgrounds and teaching duties find personal value in the program.

Practice 2: *Balanced time flexibility*: Our training offers time flexibility for participants to design their program within the maximum program duration of two years. This aims that the program fits in the participants’ busy academic schedules. At the same time, three milestones (initial talk, project discussion, program reflection) are set within an optimal program duration of one year, envisaging to help structuring their pathways.

Practice 3: *Thematically open orientation*: Our training offers a wide-range of didactic topics like research-based learning, challenge-based learning and Artificial Intelligence tools in teaching and learning. The aim is to establish alternating specific areas and to initiate sub-groups sharing interest and responsibility in certain topics.

Practice 4: *Networking among groups of participants*: Our training offers various networking options, especially the first workshop and the network meetings. This is to subdivide the start-group into participants that share the same interest, teaching level or timing to implement the teaching project. It intends to build trust and reflect on shared teaching responsibility from the beginning.

Practice 5: *Acting in teaching practice with a partner from any school*: Our program offers to conduct the complementary elements (33 h) with a partner participant committed to in the first network meeting. The aim is, that participants develop their teaching competencies on a higher level, to build a partnership with high trust and high shared responsibility, to pool resources and for sure, to foster student learning.

Practice 6: *Support by professors/ school heads:* Our program welcomes professors to take part, among others, in the second milestone meeting where project teams meet the didactic expert to discuss their ideas. The intention is to understand each professor's teaching intentions, to jointly encourage participants, to reveal network opportunities and to guarantee a sustainable implementation of this teaching project.

Practice 7: *Supervision by didactic experts:* Our program offers each participant individual supervision in at least the three milestone meetings. Each supervisor is a didactic allrounder with special expertise and is responsible for all participants from two faculties. The aim is to build a trustful cooperation, offer didactic consultation and support participants in making progress in their own program pathway.

Practice 8: *Program delivery on campus*: Our program is offered foremost as an on-campus training. This intends to support informal, trustful exchange on teaching, research, and personal matters. Some digital elements (few workshops or milestone meetings) are offered online to suit better the time scheduling of all parties.

Practice 9: *Celebrating participants' achievements*: Our program offers a closing event within a university-wide summer fiesta. The Vice-President of Academic Affairs awards the program certificates. Participants present their teaching projects in a poster fair, and the most inspiring teaching ideas are awarded by the audience. This creates acknowledgement in a more informal get-together and communicates teaching innovations to all kind of university members.

Practice 10: *Robust program structure and processes*: Our program offers a robust and impactful general structure that is supported by optimized and digitally mapped processes. On the one hand, that helps offering that extent of individual pathways. On the other hand, it enables being active when facing abrupt challenges like digital transition due to Covid-19 or artificial intelligence tools in teaching and learning.

4 CONCLUSION

This paper outlines a didactic qualification program that is positively evaluated by participants over the last few years. It also sheds some light into participants' teaching networks which includes foremost colleagues of the same school, other mid-level academics, and the partner participant whom to share teaching responsibility and having a trustful partnership with. The ten key practices of the balanced program show on the one hand that each participant can be supported to grow as a teaching personality and to master direct challenges in courses. One the other hand, it paves the way for all participants to both rely on existing disciplinary networks and to build rich teaching networks with other participants, academia and administration staff which are then the backbone to (re)act as a university community on transitioning teaching challenges for engineering education that are around the corner. The results presented here are restricted due to methodological limitations. Future studies will focus on better understanding participants' networks and practices.

What do we know about our first-year engineering students' backgrounds and experiences?

G. Buskes [1], **S. Rios**
The University of Melbourne
Melbourne, Australia

Conference Key Areas: *Engineering Skills and Competences, Recruitment and Retention of Engineering Students*
Keywords: *Self-concept, prior knowledge, first-year*

ABSTRACT

Students entering university come from a wide variety of backgrounds and experiences, with differing levels of knowledge and exposure to professional skills. However, university entry criteria typically focus on academic ability in particular subject areas such as maths and physics, but little information is known about students' attitudes and abilities in a variety of other, important domains such as attitude towards engineering, communication skills and level of interaction with peers. Self-concept, a cognitive evaluation that an individual makes and customarily maintains with respect to themselves concerning their ability in a general or a specific area of knowledge, can be used to evaluate students' perception of their attitudes and abilities across these previously unmeasured domains for academics to better understand the composition of the first-year student cohort.

In this paper, results of surveying approximately 350 first-year engineering students' self-concept across several distinct domains are reported. Exploratory factor analysis was performed on the resulting data, yielding 8 composite factors comprising of a mix of the original domains. While students strongly associated academic ability with perceived skill in mathematics, there was a surprising pair of engineering factors that emerged – one that captures 'engineering affect' and one that captures students' perceived relationship between engineering and creativity. It was also found that self-concept in peer interaction and communication skills were lowest out of the 8 identified factors. The results will be used to develop activities and programs to suit students' needs, particularly in terms of improving peer interaction and communication skills.

1 INTRODUCTION

Traditional entry requirements for engineering degrees focus on academic achievement in high school and the prior attainment of specialised knowledge in areas such as mathematics and the physical sciences. These requirements are often listed in terms of overall minimum percentile results or aggregate subject scores and the requirement that a certain amount of discipline specific units have been completed. Some degree programs also utilise entrance exams to ensure that students pursuing a given degree have mastered foundational concepts required for that program (Basavaraj et al. 2021). What these entry requirements do not reveal, however, is an understanding of the diverse backgrounds, experiences, and skill sets of engineering students. In an environment that is placing an increasing focus on the development of professional skills such as communication and problem-solving skills in engineering students (Nair et al. 2009), it is crucial to capture an understanding of students' perception of their level of these skills when they commence their degree and have mechanisms in place to track their development over time. Furthermore, there is a lack of vision of commencing students' attitudes towards learning, their sense of overall academic ability and concept of engineering. Note that these attitudes are distinct from the foundational discipline knowledge assessed through traditional entry mechanisms yet are crucial to understand, particularly in introductory engineering courses that are key to retention in engineering.

Self-concept, a psychological construct that refers to an individual's overall perception and evaluation of themselves, is a vital tool for assessing students' perceptions of their attitudes and abilities across these previously unmeasured domains (Gable 1986; Shavelson et al. 1976). A comprehensive understanding of students' self-concept can help educators better support their learning and development throughout their engineering education. To this end, this paper outlines the authors' approach to measure first-year students' self-concept across a number of important domains such as academic ability, communication skills and engineering self-concept. By undertaking this study, the authors sought to identify patterns and trends in students' self-concept that could inform the development of targeted activities and programs and cater to the diversity of student experience and self-concept, promoting a more inclusive and effective approach to their engineering education.

This study was conducted at the University of Melbourne, a leading university in Australia, where students complete a 3-year undergraduate Bachelor of Science degree followed by a specialist 2-year Engineering Masters degree, commonly referred to as a '3+2 model'. Participants of the study were sourced from a first-year general engineering course within the Bachelor of Science, which serves as a gateway to further engineering study in later years. Student experience and skill development in the course is vital for retention in engineering as students do not need to choose their major until the second year of their degree. Given a poor experience in the course, students may choose to drop out of Engineering and pursue another science major such as Physics, Chemistry or Computer Science. Additionally, with such a generalist first year, students come from a wide range of backgrounds and experiences, which has implications for ensuring equity within student project-teams. A mix of international and local students enrol in the course which further adds to the diversity of the first-year cohort.

This paper will introduce the notion and importance of assessing student self-concept and describe the development of the survey instrument. The results of conducting the survey on 350 commencing first-year engineering students will be presented and analysed. The paper will conclude with a discussion highlighting the key features of the analysis and what implications these might have on the development of student learning activities into the future.

2 METHODOLOGY

Self-concept is defined as a “cognitive evaluation that an individual makes and customarily maintains with respect to themselves concerning their ability in a general or a specific area of knowledge” (Gable 1986; Shavelson, Hubner, and Stanton 1976). It is a hypothetical construct, and has been identified as a contributing component in expectancy models of motivation, which are based on the notion that individuals will choose, and persist in doing, a task if they have a reasonable expectation for success (Pintrich and Schunk 1996). It has also been observed that academic self-concept has motivational properties such that changes in academic self-concept will lead to changes in subsequent academic achievement (Marsh and Yeung 1997).

Multiple instruments for assessing self-concept have been developed over the years that can be used with individuals from childhood through to late adulthood and have varying levels of psychometric soundness, the strength of their theoretical base, and utility in a variety of research and practice situations (Byrne 1996). The Self-Description Questionnaire III (SDQIII) (Marsh and O'Neill 1984) was originally developed for assessing self-concept in high-school students and has proven strong validity and reliability characteristics (Wylie 1989; Marsh and Shavelson 1985; Marsh 1990). The SDQIII defines 13 factors (e.g. mathematics, verbal, academic, relations with peers, physical appearance) to measure self-concept that are assessed using a 136-item questionnaire. It is not tied to a specific domain, unlike some other self-concept instruments, and as such was deemed to be an appropriate basis for developing an instrument to assess the self-concept of first-year engineering students at The University of Melbourne.

In order to assess students’ self-concept, the SDQIII was adapted for first-year engineering students in the following way:

- Five of the factors were adapted directly from the SDQIII: Mathematics (M), Academic (A), Creativity / Problem Solving (Pr), General Self-concept (G) and Honesty (H);
- A factor pertaining to Engineering (E) was created by modifying several of the SDQIII ‘Mathematics’ items to relate to engineering;
- A factor on Communication Skills (C) was created by modifying SDQIII items representing the ‘Verbal’ factor to more broadly cover communication skills, involving both written and verbal communication which are both essential for engineering students;

- A factor on Peer Relationships and Interactions (Pe) was created by adapting items from the SDQIII 'Relations with Same Sex Peers' factor, as teamwork plays an important part in first-year and subsequent engineering courses.

Ten survey items were taken or adapted from the SDQIII for each of these eight factors that were deemed most appropriate for understanding self-concept with respect to first-year engineering students. All up, there were a total of eighty items on the survey instrument and these were placed on the survey as statements in a pattern similar to that of the SDQIII – every eighth item belonged to the same subscale and items were randomly distributed by direction (positive or negative). This structure ensured that the items on the subscales were psychometrically distinct yet had strong internal consistency. A survey form was generated that asked students to rate how accurately each statement (item) described themselves and were provided with a seven-point scale ranging from "very inaccurate" to "very accurate" to perform this rating. It was decided to provide seven choices to help strengthen the reliability of the instrument and allow greater distinctions between responses (Gable 1986).

3 RESULTS

The self-concept survey instrument was administered to commencing Bachelor of Science students during scheduled class time. Students were given approximately 15 minutes to individually complete the paper-based questionnaire under exam-like conditions. All survey data were collected anonymously and students could elect to not participate in the survey by not submitting their survey to the facilitators. Overall, 350 students took part in the survey, with 294 students returning surveys to be included in the analysis, which were scanned and processed by a machine-reading program. Of these 294 surveys, 286 contained complete results and these were used as the basis of the analysis. The five most accurate and five least accurate statements, measured by the means of the item responses, are given in Table 1.

Table 1. Survey items with the strongest responses

Most accurate statements	**Mean**	**Std. Dev**
14. I am comfortable talking to other students	5.56	1.30
20. I find engineering concepts interesting and challenging	5.53	1.18
27. I enjoy working out new ways of solving problems	5.37	1.24
56. I am a very honest person	5.34	1.30
32. I nearly always tell the truth	5.33	1.37
Least accurate statements	**Mean**	**Std. Dev**
4. I have never been excited about engineering	2.21	1.26
24. Being honest is not particularly important to me	2.28	1.45
22. I don't get along very well with other students	2.3	1.24
9. I have hesitated to take courses that involve mathematics	2.42	1.59
69. In school I had more trouble learning to read than most other students	2.51	1.63

From these results it is noted that, overall, students have a strong interest in engineering concepts and enjoy solving problems in new ways. This is perhaps not surprising as the university typically attracts high-achieving students. Furthermore, Q20, Q27 and Q4 were amongst the survey items with the lowest standard deviations, indicating a level of uniformity in this sentiment. It is interesting to note that questions relating to Honesty and Peer Interaction also figure prominently in the strongest responses, potentially indicating a student body that appears to have a strong sense of integrity and personability.

Based on the instrument's original eight factors, average response values (normalised to 100%) for each could be determined across all respondents, noting that items on the survey instrument that had a negative direction were inverted on the scale. Mathematics, Engineering, and Honesty rated highest (71%, 70% and 72% respectively), while Communication Skills, Peer Relationships and Interactions, and Problem Solving rated lowest on average (67%, 66% and 66% respectively).

Overall, a composite total self-concept rating, out of 7, could be obtained via averaging results for all items for each student and then taking the average over all students. This revealed that:

- 43.9% of students rated themselves having strongly positive overall self-concept (greater than or equal to 5)
- 55.0% of students rated themselves having overall neutral self-concept (between 3 and 5)
- 1.1% of students rated themselves having negative overall self-concept (less than or equal to 3)

The original eight factors were selected to assess self-concept over dimensions deemed important for first-year engineering students. However, students were not explicitly told what these factors were, and thus further analysis was performed to indicate if survey items had similarity in patterns of responses by students and whether they mirrored the underlying factors. *Exploratory factor analysis* was used as a statistical technique to determine how particular items could be grouped together to define new, constructed *subscales* (Fabrigar et al. 1999). This was an iterative process, in that several analyses were needed to be run, each with different constraints, and then the results evaluated for interpretability. A more detailed discussion of the procedures available and the decision making process involved can be found in standard texts (Gorsuch 1983). All statistical analyses were performed using IBM's SPSS software package, version 28.

The matrix of simple correlations among the survey items contained a reasonable number of values in the range 0.3 to 0.7 with significance (2-tailed) less than 0.001, indicating the likelihood that the data set would likely factor well. To formally assess this, the Kaiser–Meyer–Olin (KMO) measure of sampling adequacy, which compares observed correlation coefficients with partial correlation coefficients, was calculated as 0.86. Kaiser (1974) recommends a minimum barely acceptable KMO value of 0.5, values between 0.7-0.8 as acceptable, and values above 0.9 as superb.

Factors were extracted using the *principal components analysis* method. A scree plot of eigenvalues and observation of the amount of variance explained by each one indicated between 7-8 strong factors. There was a clear break observed in the scree plot between the eighth and ninth eigenvalues, indicating a sensible choice of eight factors to extract. Structure was explored by extracting the eight factors using varimax (orthogonal) rotation and studying the pattern and magnitude of the loading (degree of association) of each survey item on each factor. The eight extracted factors explained 51.70% of the variance in the data set. The high degree of relatedness of the items within each factor permit the scores of these items to be combined into a single *subscale score*, shown in *Table 1*. The subscale names chosen in this table are indicative of the items that formed the factor.

Table 1 : Identified subscales and corresponding item numbers

Subscale	**Items**	**Instrument Factors**								**Average self-concept**
		M	**A**	**G**	**E**	**Pe**	**Pr**	**C**	**H**	
1. Mathematics / Academic	33, 49, 17, 25, 41, 50, 9, 34, 57, 66, 26, 65, 74, 73, 1	10	5	-	-	-	-	-	-	71%
2. General Self-concept	79, 7, 23, 31, 39, 63, 15, 47, 71, 55, 80	-	-	10	-	-	-	-	1	71%
3. Engineering Affect	60, 76, 36, 52, 4, 67, 35, 22, 54, 3	-	-	-	5	2	3	-	-	73%
4. Peer Interaction	62, 30, 70, 78, 46, 61, 14, 38, 51	-	-	-	-	7	1	1	-	66%
5. Communication Skills	77, 21, 37, 13, 69, 45, 5, 29, 53, 16	-	-	-	-	-	-	9	1	67%
6. Honesty	56, 24, 32, 64, 72, 48, 40	-	-	-	-	-	-	-	8	72%
7. Academic Sentiment	18, 2, 10, 42, 58, 43	-	5	-	-	-	1	-	-	70%
8. Engineering Creativity	68, 44, 27, 28, 20, 11	-	-	-	4	-	2	-	-	71%

Items with loadings of below 0.369 on any factor were not considered to load on it. Five items, with loadings between 0.292 and 0.369 (Q75, Q19, Q12, Q59, Q6) had no strong association with any factor and were not included in the subscale calculations. Three of these were from the original Creativity / Problem Solving scale and interestingly related specifically to creativity, indicating that students did not consider this factor independently in its own right. On the identified subscales, Mathematics / Academic, Engineering Affect and Honesty rated highest, while Communication Skills and Peer Interaction rated lowest on average.

4 DISCUSSION

Several interesting features were revealed when analysing the new subscales generated by the analysis. Of particular interest were subscales 1,3, 7 and 8 as these subscales showed interesting combinations of question groups and/or relationships between them.

Subscale 1 (Mathematics / Academic) comprised all of the mathematics questions plus several academic questions related to students' perceptions of their skill, for example "I learn quickly in most academic subjects". Both the academic and mathematics questions in this subscale were negatively aligned (positive questions have negative components and vice versa) which implies that negative perceptions of academic skill are aligned with negative perceptions of mathematics. This might reveal a relationship between perceived ability in mathematics and academic confidence and suggests benefits in building stronger confidence in mathematics in first-year students.

Subscales 3 (Engineering Affect) and 8 (Engineering Creativity) could be considered similar as they both contain a mix of engineering and problem-solving questions. Subscale 3 appears to measure an apprehension towards engineering indicated by the fact that it contains only negatively phrased questions, e.g. "Engineering Intimidates me" and "I'm not much good at problem solving", which are negatively aligned. Subscale 3 also contains two peer related questions that are also negatively aligned. This suggested the subscale was measuring a form of engineering affect.

Conversely, subscale 8 appears to measure engineering creativity and confidence in ability as indicated by a combination of skills-based problem-solving questions and engineering questions such as "I am quite good at dealing with engineering concepts". These questions are positively worded questions and are positively aligned. Unsurprisingly, both subscales strongly link problem-solving with engineering self-concept and thus improving problem solving confidence in first-year students could be key to reducing engineering apprehension and improving retention. Tracking problem-solving ability could also be a relatively straightforward method of tracking engineering self-concept.

Finally, subscale 7 (Academic Sentiment) appears to measure positive sentiment towards academic ability. The questions in this section are positively aligned and are mostly academic questions with one question relating to problem solving. These questions all relate to a students' sentiment or attitude towards academic subjects, e.g. "I like most academic subjects" or "I hate studying for many academic subjects". It is interesting to note that academic sentiment is separated from perceived academic ability, which is captured along with mathematics in subscale 1. Furthermore, academic sentiment is not aligned with self-concept in engineering, which is contrary to similar work involving engineering Masters students (Buskes 2019) who have likely had time to develop such an alignment. In future, it will be insightful to measure academic sentiment at the end of semester to see if it becomes more aligned with engineering self-concept.

Communication Skills and Peer Interaction had the lowest self-concept, with an average of 66-67%. This is likely due to the first-year cohort not yet having many opportunities to develop skills in these areas (potentially amplified through the effects of COVID-19 at high-school) and emphasises the need for more targeted development of these skills in the first-year cohort.

5 SUMMARY

In order to discover more about students' backgrounds and experiences, approximately 350 first-year engineering students were surveyed to assess their self-concept across eight distinct domains. It was revealed that students had lower self-concept in the factors of Communication Skills, Peer Interactions, and Problem Solving than in Mathematics, Engineering Affect and Honesty. Further analysis found that students strongly associated academic ability with perceived skill in mathematics and identified a pair of composite factors relating to engineering – one that captures affect towards engineering (Engineering Affect) and one that captures students' perceived relationship between engineering and problem solving (Engineering Creativity). The implementation of such a survey has permitted building a more complete picture of student self-concept, the results of which will be used to develop activities and programs to suit students' needs, particularly in terms of improving peer interaction and communication skills.

Returning to on-campus activities for first-year engineering skills development - a comparative study

G. Buskes[1], **H. Chan**

Melbourne, Australia

Conference Key Areas: *Engineering Skills and Competences. Curriculum Development*
Keywords: *Skills development, first-year, project-based, on-campus*

ABSTRACT

Prior work by the authors on student skills development detailed the implementation of a suite of skills modules in a first-year engineering course. These modules were instrumental components in supporting the course's project-based framework that offered flexibility of choice and timing in a low-risk setting. It was found that, while receiving overall favourable student feedback, most students only completed the minimum requirements and largely chose technical modules according to the relevance to their project topic.

Due to the cessation of on-campus teaching activities caused by the COVID-19 pandemic, these modules were delivered wholly online. With the lifting of restrictions the following year, the modules were made available with several distinctions: (a) the option of completing wholly online or a mix of online and on-campus activities; and (b) a change to a graded assessment scheme to encourage students to put more effort into their completion.

An evaluation performed on the modules revealed that online-only modules were attended at a rate comparable to on-campus activities. The distribution of module completions over the semester was influenced by module availability, students' time management and module alignment with their project. A higher concentration of module completions occurring closer to deadlines indicated that students were more time pressed and completed the modules just in time. A change to the grading scheme did not appear to affect the take up rates of the modules but did result in better quality of work. Students still elected to complete modules aligned with their project, consistent with previous trends.

1 INTRODUCTION

As a result of emerging from the COVID-19 pandemic, many universities that saw transitions from face-to-face to online learning during the peak of the pandemic are now having to transition back to traditional, on-campus delivery modes. During this transition, universities have adopted many different models of simultaneously supporting both online and on-campus students (Almendingen et al. 2021; Hur 2022). Hybrid styles of delivery, such as those combining online and on-campus students in design studio environments, often used in engineering, have raised issues of learner equity and access, cohort building, and negative staff and student perceptions (Thompson et al. 2021). ‘Split cohort’, or ‘dual delivery’, where online and on-campus students are treated as separate cohorts within a course and have distinct teaching streams (and possibly assessment tasks), can mitigate some of these issues, however there are still negative perceptions of such an approach, in terms of lack of face-to-face interaction with instructors and lack of support for online students (Kember, Trimble, and Fan 2022; Glazier and Harris 2021). These models typically assume that students able to attend on-campus activities must necessarily attend them, while online students are only able to attend activities in an online capacity. What is unclear, however, is what students’ preferences are when given the opportunity to *choose* between attending on-campus or online activities and whether this affects patterns of attendance, completion rates, scheduling, engagement and academic performance compared to when offered only as wholly online activities.

This paper describes how a suite of skills modules, initially introduced as online-only activities in a first-year engineering course during the peak of the COVID-19 pandemic, were adapted for a return to campus, permitting students the option to complete wholly online or as a combination of online and on-campus activities. These modules covered both technical (related to the specific design project) and general (i.e. professional) skills. Differences in patterns of behaviour between online and on-campus students across these two categories were investigated. Comparisons in student completion rates and timeliness to the wholly online mode of the skills modules that was implemented the prior year are also presented and discussed.

2 BACKGROUND

Prior work by the authors on student skills development detailed the implementation of a suite of skills modules in a first-year engineering course, Engineering Modelling and Design, at the University of Melbourne (Buskes and Chan 2022). These modules were instrumental components in supporting the course’s project-based framework, where students work on a semester-long project such as programming an autonomous robot, designing, building and testing a speaker, or simulating and mitigating the effects of a coastal flooding event. The suite consisted of four *general* skills modules – Teamwork, Report Writing, Video Production and Prototyping, designed to develop the professional skills deemed necessary for completing each project and six *technical* skills modules, developed to cover a range of discipline skills in engineering that closely aligned with the projects, namely Basic MATLAB/Simulink, Simulink Stateflow Robot Control, Circuit Theory and Analysis, Arduino, CAD & 3D Printing and QGIS. As part of the course assessment, students were required to complete at least one General skills module and at least one Technical skills module to qualify for 10% of the course mark.

The three general skills modules - Report Writing, Video Production and Prototyping were offered as self-paced, online modules developed in H5P, comprising guided activities that built towards the submission of a piece of assessment.

The six technical modules and the general Teamwork module were each originally designed as self-enrolled on-campus workshop-based sessions, where a demonstrator would facilitate a series of activities derived from the intended learning objective(s) of the particular module. During the 1.5hr facilitated workshop sessions, students would first progress through a set of guided activities and then be required to individually complete a set of specific tasks in order to be certified as having completed the module. In Semester 2 of 2021, when the skills modules were first introduced, these workshops were conducted wholly online due to COVID-19 restrictions and a pass mark was automatically awarded if a student attended the workshop and attempted the tasks, without consideration if all tasks were successfully completed.

3 CHANGES TO WORKSHOP-BASED SKILLS MODULES

With the transition back to face-to-face learning in Semester 2 of 2022, more than 90% of the students in the course reported being able to attend classes on campus. While the three general skills modules, Report Writing, Video Production and Prototyping, continued to be offered as self-paced, online modules in H5P, the workshop-based skills modules, namely the six technical modules and the general Teamwork module, had to be adapted to accommodate both online and on-campus students in the cohort. The implementation of such a hybrid delivery model provided students with flexibility in completing the workshop-based modules – the choice to either complete the modules entirely online (online preparation and online workshop session) or opt for a combination of online (online preparation) and on-campus workshop session as shown in Table 1. While the online mode of delivery was only available for those students who were unable to attend campus, both options were available to students who were able to attend campus.

Across the 12-week semester, an average of one out of four workshops were delivered online, distributed in a way that each skills module included at least one online workshop to accommodate the online students. QGIS remained the only skills module with wholly online workshops in line with the coastal flooding project which was offered as a simulation-based, online-only project.

Table 1. Delivery modes of skills modules (indicated by ‘X’)

		Mode of Delivery		
Module Type	Module	Self-paced Online	Workshop-based	
			Workshop Preparation (Online)	Workshop Session (Online / On-campus)
General	Teamwork	N/A	X	X
	Report Writing	X	N/A	N/A
	Video Production	X	N/A	N/A
	Prototyping	X	N/A	N/A
Technical	Basic MATLAB/Simulink	N/A	X	X
	Simulink Stateflow Robot Control	N/A	X	X
	Circuit Theory and Analysis	N/A	X	X
	Arduino	N/A	X	X
	CAD & 3D Printing	N/A	X	X
	QGIS	X	N/A	N/A

In the revised workshop structure, the workshop sessions maintained their 1.5hr duration, however the previous policy of an automatic pass mark for attendance and participation was replaced with a scaffolded assessment structure. Under the new structure, students were awarded a weighted mark for each of the multiple tasks they completed within the workshop session. This was implemented across both online and on-campus workshops as motivation for students to complete all the tasks to fulfil a particular skills module’s intended learning outcome(s).

4 EVALUATION AND DISCUSSION

In Semester 2 of 2022, the multiple delivery modes for the skills modules were offered to a hybrid cohort of 344 students, of which 25 were online-only students who were unable to attend any classes on campus. A comparative analysis was conducted to observe module completion trends between the wholly online cohort of 2021 versus the hybrid delivery cohort of 2022, where students had the option to attend the workshop sessions either on-campus or online.

4.1 Completion rate of skills modules

A comparison of the completion rates of the skills modules between 2021 (wholly online) and 2022 (hybrid) cohorts is shown in Table 2, where the 2022 hybrid cohort is further broken down into students who indicated they were not able to attend campus and those who indicated they were able to (but could chose not to).

Table 2. Completion rate of skills modules

Cohort	**% who completed at least one module**	
	General module	**Technical module**
Wholly online cohort in 2021	81.0%	86.7%
Hybrid cohort in 2022	88.9%	89.0%
- Students unable to attend campus	84.0%	56.0%
- Students able to attend campus	90.3%	91.5%

There was a slightly higher overall completion rate of both types of module in 2022 compared to 2021, however, when examining the breakdown of the 2022 data, it was observed that the completion rate for the Technical modules among students unable to attend campus was significantly lower at 56%. This contrasts to the on-campus students who achieved a much higher completion rate of 91.5%.

This discrepancy could be attributed to several factors. Firstly, on-campus students were familiar with the learning spaces hosting the on-campus workshop sessions and could conveniently attend the Technical module workshops after one of their other classes. Additionally, on-campus students had a broader range of workshop session times to choose from due to expected demand and thus had more options and flexibility in scheduling their workshop sessions.

In contrast, online students were perhaps disadvantaged by the limited number of online workshops offered during the semester, with only one online workshop session available for most technical modules. Motivation also likely played a role in the lower completion rate among online students. Unlike on-campus students, online students lacked the opportunity for face-to-face interaction with peers. As a result, they may have missed out on an element of peer encouragement and motivation, which can often be influential in completing workshop assessments.

The overall cohort completion rate for the Technical module of over 86% remained largely consistent from 2021 to 2022. This suggests that the introduction of task-based assessment components into the Technical workshop sessions did not affect the completion rate. In fact, informal discussions with students and demonstrators revealed that students were more motivated to complete all the tasks in the workshop, indicating that the assessment tasks served their purpose in facilitating student learning and ensuring that all learning objectives were fulfilled.

Further analysis of the 2022 cohort's completion of different combinations of the general and technical skills modules unveiled that a majority of students, comprising 85% of the cohort, completed only the minimum requirement (of one General and one Technical module) to achieve the skills module mark - a similar trend to the 2021 cohort. However, there was a slight increase of 1.5% in the number of students who completed more than the minimum requirement in 2022 compared to the previous year. The majority of students focused on meeting the minimum requirements, suggesting that the cohort generally aimed to fulfil only the necessary criteria to obtain the skills module mark. While some students demonstrated an inclination to go beyond the minimum, the overall completion pattern remained consistent with the previous year's cohort.

4.2 Uptake of skills modules workshop sessions

An evaluation of weekly workshop session subscriptions revealed that among the on-campus students, approximately 80% completed their workshop-based skills modules in the on-campus workshops, while the remaining 20% completed them online. Figure 1 shows the average percentage of subscriptions to on-campus and online skills modules workshops in 2022, computed from the ratio of the number of attendees to the workshop capacity limit. Based on the orange and blue bar-pairs in Figure 1, the average subscription rates between the on-campus and online workshops were surprisingly comparable, with a few exceptions - the Arduino module recorded zero subscriptions to the online workshop and the QGIS modules were exclusively offered online.

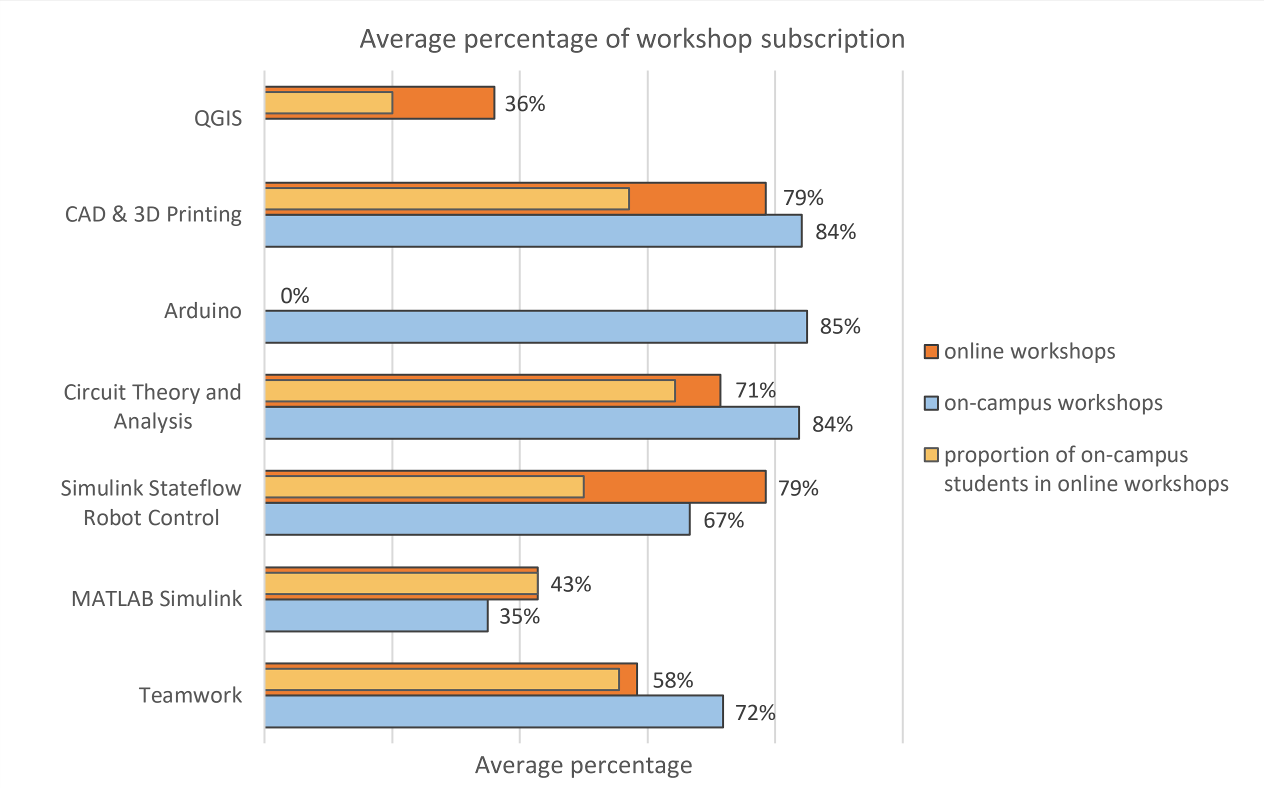

Fig. 1. Average percentage of workshop subscription in 2022

Within the online technical workshops, on average approximately 70% of attendees were on-campus students who chose to complete their modules online, represented by the yellow bars within the orange in Figure 1. It is worth noting that two outliers were not included in the observation: (1) 100% of the MATLAB/Simulink online workshop attendees were from the on-campus cohort, while (2) the online Arduino workshop had zero attendees, indicating a clear preference for on-campus attendance for this specific module. Significant on-campus student subscription to certain online workshops such as those involving Simulink and CAD, suggests that students were not opposed to attending online sessions for modules that had heavier emphasis on computer-based activities. On the other hand, students preferred the on-campus workshop for the Arduino module, which entailed programming hardware as opposed to simulation.

The online general Teamwork module subscription was dominated by on-campus students at the rate of 95%, mainly because the last Teamwork workshop was offered online at the end of semester and students had no alternative if they wanted to complete the module as part of the General module requirement.

In terms of subscription rates, the MATLAB/Simulink module did not attract as high an interest as the other modules, partly because this module was offered towards the first half of semester to provide basic knowledge in Simulink. Students in the Autonomous Robot project stream likely found that there was no longer a need to attend this basic module past Week 3 once they were well underway in their project. The QGIS workshops, offered fully online, were also poorly subscribed due to the very specific nature of the module only associated with the Coastal Flooding project and the small number of students in that project stream.

4.3 Timeline of skills modules completion

The completion of technical skills modules largely aligned with the particular projects, reaffirming the observations from the 2021 cohort (Buskes and Chan 2022). There was no discernible trend for when students chose to complete the modules with workshop components (i.e. the Teamwork and the technical modules) as uptake was reasonably distributed over the semester weeks, depicted by the solid blue coloured columns in Figure 2.

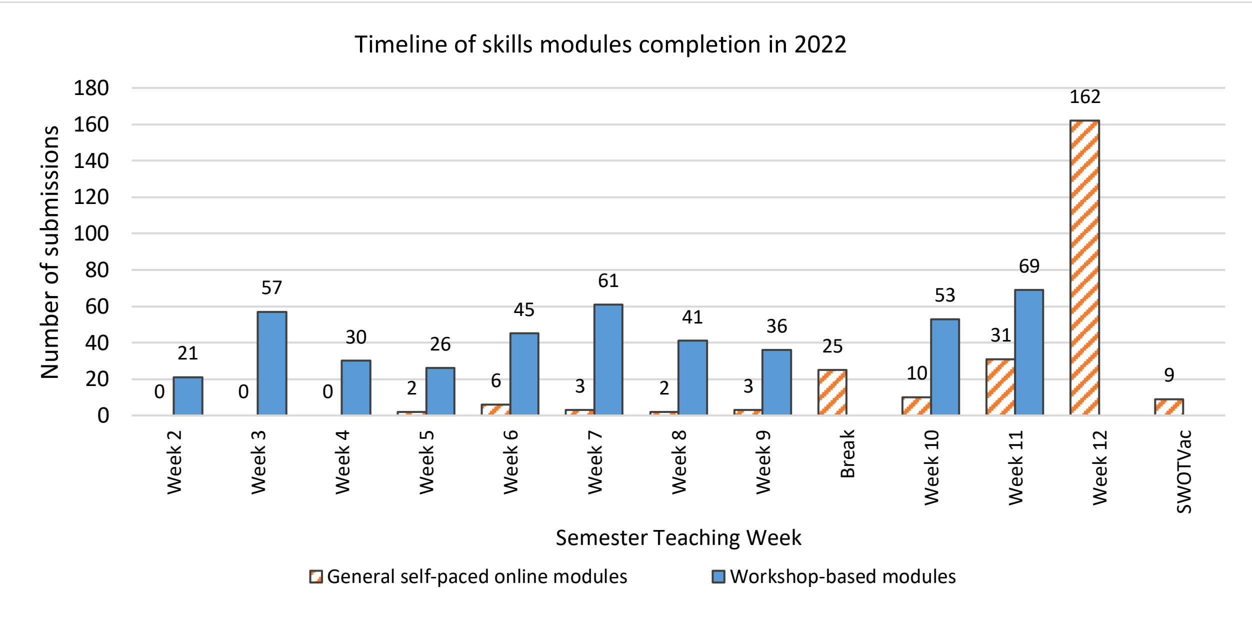

Fig. 2. Timeline of skills modules completion in 2022 (hybrid)

The general trend in 2022 was that higher module uptake occurred in weeks when more workshops were offered, suggesting that students tend to take up the technical modules at their convenience aligned with the availability of workshops. The peak in

Week 11 was likely the result of students rushing to fulfil the minimum skills module completion requirement before the workshops ceased.

There was a notable lack of completion of the general online self-paced modules throughout the semester until around Week 11 the, as shown by the orange patterned columns in Figure 2. A sudden surge in submission numbers occurred in the final week of the 2022 semester, which was the deadline for the general skills modules. The observation suggests that students from the 2022 cohort tended to prioritise completing modules with a workshop component first, as there are limitations to workshop offerings and availability. As a result, online self-paced modules were left to the end of semester when students were likely pressed for time. In 2021, the spread across semester was broader and not as concentrated in Week 12, which could be attributed to the additional flexibility that students had with wholly online learning and that they had more available time to spare by not having to travel into the campus during lockdown conditions.

5 CONCLUSION

With a hybrid cohort in 2022, the high completion rate of the workshop-based skills modules among on-campus students contrasted with the low rate among online students, suggesting that self-motivated enrolment into workshops is more effective when there is campus interaction among students. This is encouraging for future offerings of the course, with all university degree programs moving back to fully on-campus cohorts over the next year. With two delivery modes of workshops offered, on-campus students were not opposed to the option of online workshops for modules that are mainly computer-based, but preferred to do them on-campus if there was a hardware element involved. It was encouraging that the introduction of an assessment component in the workshops provided motivation to complete all workshop tasks and did not deter students from attempting or completing the modules. From the outcomes of the study, two areas for future improvements were identified: (1) planning of workshop offerings in future should be reviewed to avoid having too many undersubscribed workshops; and (2) considering offering an incentive to encourage earlier completion of the self-paced online general modules to bridge the significant gap between the completion time of the general and technical modules across the semester.

ABSTRACT

The experience carried out at the University of Florence, Department of Civil and Environmental Engineering, in designing two new undergraduate curricula in "Environmental Engineering" and "Civil and Building Engineering for sustainability", is reported. The bachelor in Environmental Engineering aims to train engineers capable of working in the field of protection of environment, territory and natural resources. The bachelor in Civil and Building Engineering for sustainability aims to train engineers capable of working in the field of structures, infrastructures, and constructions in general, as well as management and safety of construction processes. The development of the two curricula was based preliminarily on a national and international survey of degree programs of the same type and with shared learning outcomes. Subsequently, labour market needs were identified starting from discussions with all stakeholders, students and professors included. Teaching methods and methods for assessing students' preparation have also been revised and the teaching plan of both curricula is characterized in the third year by the presence of multidisciplinary laboratories, focused on the most characterizing themes of each

[1] *Corresponding Author*

programme and the different disciplines with integrative and specific in-depth characteristics. Finally, a thorough design of the two courses contents has been initiated, based on the definition of the general educational objectives and the specific disciplines.

---

1 INTRODUCTION

Climate change and environmental degradation are now globally perceived as the greatest threat to Europe and the world: national and supranational institutions are pursuing strategies for a resource-efficient economy to face the challenge of sustainability. In particular, the European Commission through the "European Green Deal" (Fetting 2020) marks the roadmap to make the EU economy sustainable and aims to achieve this goal by transforming climate related problems and environmental challenges (environmental sustainability, resilience, decarbonisation, etc.) into opportunities with economic growth that is decoupled from the use of resources, with no person and no place being neglected.

The strategic objective is to transform Europe into the first block of countries with zero climate impact by 2050 (IPCC 2022). In this context, it is therefore necessary to strengthen and expand professional skills in numerous areas typical of civil, building and environmental engineering. The policies for the so-called "ecological transition" and the European directives on the circular economy, which have a prevalent part in the Recovery Fund, in order to be implemented need adequate financial instruments, and, above all, qualified and trained personnel to address these challenges.

The establishment of new degree courses is therefore perfectly in line with the strategic development guidelines of the European Commission envisaged in the Next Generation EU Plan and with the Italian National Recovery and Resilience Plan, which identifies the "Green revolution and ecological transition" and the "Infrastructures for sustainable mobility" among the six structural thematic areas of intervention.

In this context, the Department of Civil and Environmental Engineering (DICEA - *Dipartimento di Ingegneria Civile e Ambientale*) of the University of Florence has found the reasons to propose, starting from the A.Y. 2023-2024, the activation of a new Degree Course in Environmental Engineering (*Ingegneria Ambientale* - IAL), in the degree class L-7 Civil and Environmental Engineering, focusing more on the specific contents of Environmental Engineering and a strong revision of the current three-year degree in Civil, Building and Environmental Engineering, developed on three curricula: civil, building and environment. This existing course was deeply modified, starting from the name, which from 2023/2024 will be changed into Civil and Building Engineering for Sustainability (*Ingegneria Civile e Edile per la sostenibil*ità - ICE), and including all its most fundamental aspects (e.g. learning outcomes, career opportunities, study programs, etc.) with the aim of effectively defining a brand new course of study.

In designing the newly established IAL study program and revising the existing one, reference was made to the needs for innovation and sustainability coming from the labour market and, at the same time, to the priorities and objectives to which the University of Florence inspires its strategy of qualification and sustainability of the educational offer.

The review of the educational offer as a whole also stems from the results of a survey carried out to analyse the placement of graduates in civil engineering, building engineering and environmental engineering in the labour market (AlmaLaurea 2023), as well as it emerges from the investigation preliminarily carried out at national level on the three-year degree courses in the degree class L-7 Civil and Environmental Engineering.

The new study program and the revision of the current one are consistent with what observed in the largest Italian universities as well as in prestigious foreign universities, such as Harvard University, Stanford University, University of Cambridge and ETH Zurich.
From a methodological point of view, the definition of the two programs is in line with the solicitations coming from the world of industry and professions (Duderstadt 2010; Eckert et al. 2019; Van der Vleuten et al. 2017), and with the results of the surveys conducted by prestigious engineering training schools which have begun to question on the challenges that fast societal change poses to engineering education (Graham 2018).
In particular, attention was paid to the period of great change in the training of engineers in order to respond adequately to the demands of society. The change includes engineering study programs with a more relevant social-education component and with a greater focus on skills. Greater flexibility for students in the composition of their curricula, greater attention to multidisciplinary learning, increased students' awareness of the impact of technologies on the socio-economic context, and greater attention to the acquisition of soft-skills, are also fostered.
A study by UCL (2018), in this regard, reveals the importance of associating "soft-skills" with the "hard-skills" typical of engineering education, to focus on "inclusion and diversity" through more inter and multi-disciplinary curricula, focusing on disciplines that concern the development of an engineering career, the acquisition of know-how skills through the development of real projects and the growth of the international dimension through experiences abroad.
Formally, whether it is a newly established program or the revision of an existing program, the first phase of planning concerns the definition of learning outcomes, i.e. the set of knowledge and skills that characterise the cultural and professional profile, to which the curriculum is aimed at. This is followed by the definition of the specific Didactic Regulation for the Degree Course, i.e. the set of rules that regulate the specializations or curricula of the study programme, according to the University teaching regulations, drawn up in compliance with the reference legislation.
The final phase concerns the definition of the specialisations or curricula in which the degree course is organized and the set of university and extra-university training activities specified in the teaching regulations of the degree course for the purpose of obtaining the relevant qualification.
In the following, the methods on which the design of the new degree course as well as the revision of the existing one are based, are briefly described. The description concerns the national and international point of view on the central role of engineering degree courses and of engineers in framing the society of knowledge. The engineering education able to support and promote the changing is also discussed. The results achieved are finally described.

2 METHODOLOGY

The labour market becomes the privileged reference in the definition of training courses. In fact, there are numerous studies that have as a final result the definition of the professions that society will need in the future (WEF 2020).
Among the professions identified as strategic for the future, some are certainly attributable to the field of engineering (NAE 2017).
Nevertheless, some difficulties for engineering training schools in meeting the needs of a rapidly evolving society that poses global challenges, such as environmental and economic sustainability, protection and safeguarding of health and the environment are recognized. In the context of such challenges, the role of the Engineer is to imagine, implement and manage the technical infrastructure for sustainable change

and therefore the training and qualification of the engineers of the future plays a central role for the construction of the knowledge society (Morell 2010; Apelian 2007).
Specifically, among the challenges, the following can be traced back to ICE and IAL degree courses: i) provide access to clean water; ii) restore and improve urban infrastructures; iii) assess life-cycle of materials and structures; iv) use innovative and recyclable materials; v) design Nearly Zero-Emission Building (NZEB); etc.
Thus arose the need to respond to the necessities expressed by society with knowledge, skills and attitudes developed by students during their training in engineering schools for modern professional figures of engineers who know how to support and promote sustainable change. In this context, the learning outcomes of the two degree courses have been defined with reference also to the recommendations reported by ASME (2023) on: a) development of higher standards of professional and communication skills; b) increased flexibility in the study programmes. The definition of the learning outcomes, however, concerns the characterization of the cultural and professional profile, i.e. the set of knowledge and skills each curriculum aims to provide. Once the professional profiles and learning outcomes have been defined, the construction of the didactic regulation of the degree course is required. Each teaching regulation determines: a) the denominations and educational objectives of the study courses, indicating the relative classes to which they belong; b) the general framework of the training activities to be included in the curricula; c) the credits assigned to each training activity and to each area, referring them to one or more scientific-disciplinary sectors as a whole; d) the characteristics of the final exam for obtaining the degree.
Every year the Italian *National University Council* (CUN 2022), with reference to the regulatory context and the ministerial indications for the quality assurance of the Degree Programmes, provides indications for an effective drafting of regulations and the elaboration of a valid and well-structured teaching offer. On the basis of the regulation that constitutes the general framework of the Degree Course, different curricula may be developed within the same Course.
Both degree courses have been divided into three curricula that represent different education paths, but are aimed at achieving the same training objectives. Each curriculum is aimed at directing the training of students towards one of the professional profiles identified and to acquire skills directly usable in the world of work.
Also, as required by Italian Ministerial Decree No. 133/2021, the teaching plan is characterised by high flexibility.
Besides all the aspects described above and the specific disciplines of engineering, the contents of the two degree course are defined to adequately respond to some of the Sustainable Development Goals defined by the United Nations in the 2030 Agenda, namely: SDG 9-Industry innovation and infrastructure; SDG 11-Sustainable cities and communities; SDG 13-Climate action. The SDGs in IAL are integrated with: SDG 6-Clean water and sanitation; SDG 14-Life below water; SDG 15-Life on land.

3 RESULTS

The Degree Course in *Civil and Building Engineering for sustainability* aims to train first-level engineers of the degree class L-7 Civil and Environmental Engineering that add to the solid traditional technical training, also the ability to contribute to the sustainable development of the territories and the communities within which engineering works fit, ensuring that technological applications are consistent with the needs of future generations.
Classes which refer to the contents of the most characterising disciplines of civil and building engineering, suitably organised, so as to train technicians with a highly multidisciplinary preparation, essential for responding to the needs expressed by the

labour market and by a multiplicity of stakeholders and higher academic education, with particular reference to the following areas:

a) design, construction and operation of buildings and structures taking into account the sustainability of exploitation of natural resources and the possibility of recycling or reusing materials and waste;
b) design of hydraulic and geotechnical civil works;
c) planning, management and maintenance of works, plants, infrastructures and urban and territorial systems, and of civil systems and installations for the environment and the territory, also for the purpose of prolonging the life cycle and sustainability of the impacts generated;
d) acquisition and management of geospatial data;
e) management and safety of construction processes.

Three professional profiles with multiple professional outlets have been identified:

- Technician of structures, infrastructures and civil works;
- Technician for buildings and building systems;
- Technician for the management and safety of construction processes.

The course is then structured in three curricula (Table 1.1, 1.2 and 1.3), aimed at covering the main application areas of civil and building engineering and at training students towards one of the professional profiles identified:

1. <u>*Structures and Infrastructures*</u>: aimed at training technicians capable of operating in the field of structures, infrastructures and civil structures, through the use of both traditional and innovative, eco-compatible, recycled systems and materials and the integration of technologies based on renewable energy and water reuse;
2. <u>*Building systems*</u>: aimed at training technicians capable of operating in the field of building systems, using traditional and innovative techniques and materials, in the context of sustainability, from both an energy and environmental point of view;
3. <u>*Construction safety management:*</u> aimed at training technicians who have knowledge and skills in the management and safety of construction processes, also with attention to the concept of social sustainability.

The Degree Course in *Environmental Engineering* aims to train first-level engineers capable of operating in the field of environment, territory and natural resource protection.
Classes referring to the contents of the most characteristic disciplines of environment and territory engineering are provided, suitably organised, so as to train technicians with a highly multidisciplinary preparation, indispensable for responding both to the needs expressed by the labour market and by a multiplicity of stakeholders, and to higher-level academic training, particularly in the following areas:

a) prevention, control and remediation of the negative impacts on the environment of the various human activities,
b) environmental impact assessment of structures, infrastructures, urban areas, production activities and services,
c) prevention, monitoring and rehabilitation of hydrogeological instability phenomena and slope instability, management of river basins and the coastal environment,
d) management of natural resources with a view to sustainable development,
e) technical-managerial coordination in the context of optimal integration of processes related to Health, Safety and the Environment.

Three professional profiles with multiple professional outlets have been identified:

- Technician of Health, Safety and Environment (HSE);
- Technician for the protection of natural resources and sustainable development;
- Technician for the assessment and mitigation of natural and anthropic risks.

The Course is structured in three curricula (Tables 2.1, 2.2 and 2.3), aimed at covering the main application areas of environmental engineering and at training students towards one of the professional profiles identified:

1) *Safety, health and environmental quality*: aimed at training technicians who have knowledge and skills to support and verifying the full and integrated implementation of processes related to health, safety and the environment with the aim of contributing to the overall efficiency of companies/organisations;
2) P*rocesses and technologies for sustainable development*: aimed at training technicians capable of technical support during the construction and operation of technological plants, whether private or public utility, for the supply of drinking water and the treatment of wastewater, solid and liquid waste and gaseous emissions;
3) *Monitoring of the territory and mitigation of natural and anthropic risks*: aimed at training technicians capable to collaborate in all activities related to the surveying, management and protection of territory and urban areas also in the context of climate change.

According to the provisions of the D.M. 270/2004, the two Courses are structured in 3 years during which students must acquire 180 credits.
The teachings of the first year are almost entirely in common among all curricula and between the two Degree Courses. The second and third year, on the other hand, provide for each Degree Course teachings in common and others specific for each curriculum. Both courses and curricula require the presence of at least 12 ECTS freely chosen by the student, the assessment of the knowledge of English language (level B2), an internship in the third year and a final exam of 3 credits. The internship is 3 ECTS with the exception of IAL-HSE which has an internship of 6 ECTS.
The study plan also includes the presence of multidisciplinary laboratories, all located in the third year, focused on the most characterizing topics of the Degree Course and teachings with a supplementary and specific in-depth nature.

ABSTRACT

The design of user interface is an important and challenging topic for student designers to understand and master. The eight principles of good User Interface (UI) design are often taught using primarily cognitive approaches, which can leave room for improvement in students' ability to apply the principles in a variety of contexts. Game-based learning tools are recognised to be beneficial in university classrooms across a variety of discipline areas and topics due to their capacity to increase engagement. This project presents a first prototype for an instructional tool that leverages constructionism and embodied learning to enhance students' understanding and application of these principles. This tool takes the form of a board game, thus encouraging peer learning. To test the prototype, three usability tests were carried out. Each user group was unique, the first being internal to the design team, the second having some prior exposure of the subject, and the third, having no prior experience at all. In each sessions, the participants were presented with a series of UI challenges, for which they were asked to construct suitable design solutions. Following the sessions, and where possible, the quality of these solutions were evaluated against a scoring system. This initial study suggests that instructional board games may be flexible enough to support learning outcomes at various stages of knowledge and skills acquisition among different learner groups.

1 INTRODUCTION

1.1 Background & Rationale

A User Interface (UI) is a device that yields the capacity for a user and a system to interact or collaborate. This device is most often a graphical user interface (GUI), but more and more, a UI can also take the form of a voice-controlled interface (a VCI) or a gesture-based interface (GBA). UI design is the process of designing these devices. There are eight principles of good User Interface design (Schneiderman, et al. 2016). These principles, along with a description and examples, are listed in Table 1. In this upcoming collaboration project between The Technical University of Denmark (KT.DTU) and Technological University Dublin (TU), we are designing a gamified framework to develop an integrated approach to teach the principles of good User Interface design. For our first design iteration, we have selected principles 1 & 2, Strive for Consistency and Seek Universal Usability, as our primary focus. With respect to principle 2, Seek Universal Usability, it can be challenging for early designers to ignore their own instincts, perceptions and intuitions whilst establishing product needs. Developing an objective or empathetic approach can assist in overcoming this challenge (Leonard and Rayport 1997).

Game-based learning tools can be beneficial in university classrooms, not least because of their capacity to increase engagement (Justo, et al. 2022). Indeed, this study also serves as an exemplar of how student engagement increases with such activities. Our proposed instructional game aims to leverage the advantages of embodied learning to enhance students' understanding and application of the eight principles of UI design. More precisely, it proposes to augment a constructionist-inspired game with multisensory interactive learning mechanics using mixed reality technologies.

1.2 Literature

Our proposed product concept draws on two education discourses; constructionism and multi-sensory learning.

Constructionism is a pedagogy where learning occurs as a process of constructing an intelligible entity (Griffin 2019) (Papert 1987). De-constructionism is a pedagogy that is inspired by and related to constructionism, however in this case, a backward-engineering technique is utilised for learning (Griffin 2019). Constructionism is a common approach for teaching User Interface design (Khoo 2011) and it is our intention to use it to underpin the gameplay of our intended product.

From birth and throughout human development, cognitive, motor and social abilities emerge together. They are connected and complementary and exert influence on one another in a variety of different ways and contexts (Thelen 1992) (Adolph and Joh 2007) (H. C. Leonard 2016). In several studies in the field of cognitive science, it has been shown that the brain weighs individual external sensory cues according to their relative precision, and constructs a reliability model for sensorimotor control (Limanowski and Friston 2020) (Körding and Wolpert 2004) (Ma, et al. 2006) (Bestmann, et al. 2008). Cognizant of this nature, multisensory learning encourages teaching methods that utilise diverse motor and sensory interactions (Davis and Francis 2023). An example of where this has been exploited in teaching is in a technique known as enrichment, where acquiring vocabulary for a foreign language can be enhanced by coupling physical gesturing with traditional verbal activities (Mayer, et al. 2015). Guided by the concept of 'walking in someone else's shoes', multi-sensory learning approaches will be used to inform the game mechanics of our intended product.

Table 1. The eight principles of user interface design

#	Principle	Description	Example(s)
1	Strive for Consistency	Employ consistent layouts colours and fonts throughout.	The location of the menu should be the same on every page.
2	Seek Universal Usability	Design for diverse user groups	Cater for Novice and Experienced, International, visual or dexterous impairments.
3	Offer informative feedback	For every action, there should be interface feedback	
4	Design Dialogue to Yield Closure	Design for events that involve several steps (a group of actions)	E-commerce websites move users from selecting products to the checkout, ending with a clear confirmation page that completes the transaction
5	Prevent Errors		Users should not have to retype an entire name-address form if they enter an invalid postcode.
6	Permit Easy Reversal of Actions	As much as possible, actions should be reversible	Press a back button to delete data from a data entry box
7	Keep Users in Control	Users should be able to achieve their desired results	
8	Reduce Short Term Memory Load		Avoid interfaces in which users must remember information from one display and then use that information on another display

2 METHODOLOGY

2.1 Framework

The overall aim of this project is to develop an instructional design tool that is both useful, attractive and either superior or complementary to the current state of the art. User Centred Design (UCD) is an established iterative process that can be employed to support product development. Here, UCD lends itself to secondary and generative research methods, which are useful for concept development. Further, UCD is also compatible with investigative and analysis-based research methods, which are useful for product testing at various stages of design development. Our method is informed by the UCD process and is illustrated in fig. 1. Stage 1 of our method serves to deliver a design concept and will be illustrated in section 3 of this paper. Stage 2 is concerned with usability testing and will be presented in section 4. Stage 3 addresses design iterations and involves cycling through stage 1 & 2, until the design has been refined.

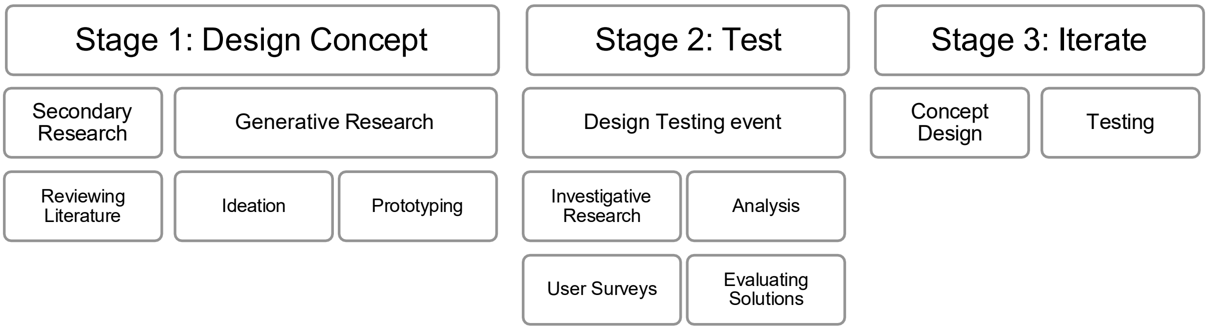

Fig. 1. Methods Diagram

3 CONCEPT DESIGN

3.1 Game Assets

A carbon tracker was selected as the subject for our game-based tool. There is no particular reason why. The tool would be just as effective had we chosen any other subject. In a brainstorm session, 7 unique features were identified that appeared to reasonably constitute a complete application (Table 2). For our initial product mock-up, and to speed up the design phase, we limited our focus to just three of these features, namely, Navigation, Calendar and Tracker.

Table 2. Features for the Carbon Tracker App concept, indicating

#	Feature	Variations	# UI Elements	Mock-up Ready for Review?
1	Navigation	1	13	Yes
2	Calendar	1	11	Yes
3	Tracker	1	13	Yes
4	Methods	2		
5	Moderators	1		
6	Options	3		
7	Metrics	2		

To facilitate the challenge we designed three distinct assets, a collection of diverse UI elements, a UI Design board, and, a set of UI Challenge cards. The UI elements are a collection of pre-designed template pieces that, like with a jigsaw, can be used to construct a complete picture for a user interface design. The UI Design Board is a poster style collaborative work tool that facilitates the organization of the UI elements. The UI challenge cards direct the goals of each round of the game. Examples of these challenges are as follows:

- Construct a suitable UI for a User who is visually impaired
- Construct a suitable UI for a User who is new to digital technology
- Construct a UI Design that conserves screen space
- Construct a UI design that minimises cognitive load
- Construct a UI Design that is consistent in its design composition
- Construct a UI that is inconsistent in its design composition

A printable version of the game is available for download on our github repository here The UI Game Board.

3.2 Game Rules

The instructions for the game were conceived as follows:

1. Populate The UI Board with the UI elements
   a. Separate the elements into two groups, Icons and Text.
   b. Separate the elements in each group by feature
   c. Organize the Icon elements by size
   d. Organise the Text elements by size and function
2. Populate the blank UI Interface with appropriate UI elements
3. Pull a challenge card
   a. Using elements from the UI Board, construct an appropriate corresponding UI design

3.3 Scoring

The initial mock-up addressed three features. For each feature there was, on average, 12 UI elements to choose from, culminating in a total of 36 pieces. With a view to establishing a method to evaluate the participant's designs, each element was categorised according to several criteria (Table 3). Using these criteria, the number of unique combinations that emerged was 22.

Table 3. UI element categories

#	Group	# Variations	Options
1	Type	2	Icon, Text
2	Size	3	Small, Medium, Large
3	Font	2	Sans, Sans serif
4	Contrast	3	Low, Medium, High
5	Interaction	3	Expand, Dropdown, Select

Subject to our current stage of development and where appropriate, each element was also given a score based on their suitable application for each challenge in the challenge card deck. Here, the assignment varied from poor to excellent across a 4 point Likert scale.

The scores for two challenges, to design a UI for (1) a user who is visually impaired and (2) to conserve space, are now complete. The main criteria for assigning these scores related to the elements size, font and contrast. For example, a UI element would have to exceed a minimum size threshold to score high on a challenge to design for a user who is visually impaired. Conversely, the same UI element may score low on a challenge to conserve screen space.

A process of developing scores for challenges that are concerned with design consistency and cognitive load are currently underway. As designing for consistency is a product of the position of and the similarity between elements, and cognitive load is impacted by levels of detail and variability, we will need to engineer a scoring matrix to evaluate these challenges reliably.

4 TESTING

4.1 Usability study

Table 4. Summary of Testing Sessions

#	Participants	Count	Participant Configuration	Date
1	Members from the Project Team	2	Individuals	15/04/23
2	Students from Y3 of the Product Design undergraduate programme at TU	6	Pairs	19/04/23
3	PhD scholars, Postdocs and faculty from the PROSYS research centre at DTU	17	Teams of 5-6	27/04/23

We conducted a usability study comprised of three sessions, a summary of which is provided in Table 4. Each of the sessions built on insights garnered from the one before. The first session was internal to our design Team where the participants were very familiar with the vision of the project. As such, we will exclude this session from further discussion. The process for session two and three is outlined below.

4.1.1 Session 2

1. A facilitator presents the 8 principles of User Interface Design
2. The concept and aims of the game are introduced.
3. Round 1, each team:
    a. Receives a randomly selected challenge card
    b. Constructs a corresponding UI design
    c. Presents their outputs and discusses the rationale with the rest of the group and tutors.
4. Round 2, each team:
    a. Receives the same challenge card – one for a user who is visually impaired
    b. Constructs a corresponding UI design
    c. Presents their proposals and the rationale for same
5. Each team fills out a feedback sheet, including observations made in the presentations.

4.1.2 Session 3

1. A speaker presents a talk on Cognitive Load Theory, Embodiment, and, this UI design Project
2. Game packs are distributed
3. Working as a group, each table:
    a. Organises the UI elements according to the UI Design board format
    b. Selects a challenge card from the challenge card deck
    c. Constructs a corresponding UI design
    d. Repeats, if time permits

3\. Each table collectively fills out a feedback sheet

For clarity, the key differences between session two and three are illustrated in Table 5.

Table 5. Variability between Testing session two and Testing session 3.

#	Variable	Level 1 Learners	Level 0 learners
1	Lecture / Talk (Primer)	The Principles of User Interface Design	Cognitive Load Theory & Embodiment
2	UI Design Board Activity	No	Yes
3	Present & discuss results	Yes	No

4.2 Investigative Research

A survey for the testing sessions was designed to establish the following:

- The base competency of the participants
- Which variables (e.g. activity, tool, instructor, peer) are perceived as having value for teaching
- Participant sentiment in relation to -
  - The suitability of the teaching approach
  - The pleasure of learning this way
- The quality of the instructional tools in relation to:
  - Ease of use
  - Perceived purpose
- The existence or otherwise of any unexpected use cases

5 RESULTS

It is important to bear in mind that the testing sessions were subject to high variability. Further, the level of subject exposure differed between the undergraduate students who participated in session two and the PhD scholars, postdocs and faculty who participated in session three. Therefore, and hereafter, we will distinguish the participants from session two and session three as level 1 learners and level 0 learners respectively, where level 1 denotes prior subject exposure consistent with an introduction and level 0 denotes no prior exposure at all.

Due to the limited extent of the scoring feature of the current prototype, we will also limit the quantitative analysis of the participant's designs to round 2 of session two. The main reason for doing so is that only the Level 1 learners integrated all of the available features into each of their solutions. Whilst the Level 0 learners did not produce designs that were substantial enough to evaluate, at the same time, the session facilitators were able to garner some insights through dialogue. For example, one Team who were challenged to design a UI for 'users new to technology' deliberately selected Text elements instead of Icons to increase familiarity. In another example, a different Team who were challenged to design a UI to 'reduce cognitive load' constructed a fuss free UI using large elements for a single feature.

5.1 Solution Evaluation

In round 2 of session two, three teams of two participants were challenged to design a UI for a user with a visual impairment. All three teams performed well and the solutions are illustrated in fig. 2. Scores for each design are set out in Table 6 whilst a short interpretation regarding the quality of each design is discussed forthwith.

Fig. 2. Testing session 2, Round 2, Results for the challenge to design a UI for a visually impaired user

Table 6. Scores for the challenge to design a UI for a visually impaired user

Element ref	Score	Team			Element ref	Score	Team			Element ref	Score	Team		
		1	2	3			1	2	3			1	2	3
f1	*1*				*t1*	*4*	**4**			*c1*	*1*			
f2	*1*		**1**		*t2*	*1*				*c2*	*4*	**4**		
f3	*4*				*t3*	*4*				*c3*	*1*			
f4	*4*				*t4*					*c4*	*1*			
f5	*1*				*t5*	*2*				*c5*	*2*		**2**	
f6	*2*			**2**	*t6*	*-*				*c6*	*4*	**4**	**4**	
f7	*4*			**4**	*t7*	*2*				*c7*				
f8	*1*				*t8*	*2*				*c8*	*2*			
f9	*1*				*t9*	*1*				*c9*	*1*			
f10	*1*				*t10*	*2*			**2**	*c10*	*1*			
f11	*2*				*t11*	*4*	**4**	**4**	**4**	*c11*	*4*	**4**		**4**
f12	*4*	**4**	**4**		*t12*	*4*	**4**							
f13	*-*													

Team 1 took an approach to provide users with the flexibility to work with minimal or maximal content at any given time using ‘show and hide’ functionality. Whilst the elements were a mix of icons and texts, the size, contrast and font options were a good choice for their intended user.

Team 2 took a creative approach and extended the UI design features using drop down functionality. Coupled with the medium sized calendar option, the image suggests that a design choice to conserve space may have been in operation.

Team 3 appear to have prioritised consistency, demonstrated in their commitment to using icons for all features in both designs. Only one of their designs includes an element for the calendar function. The sizing of this calendar block is more consistent with the medium sized icons, and is located accrodingly.

5.2 Participant Survey

A survey was designed to elicit qualitative responses from participants at our testing sessions. For the questions that correspond to 1, 2, 3, 4 and 5 in figure 4, participants were given the options Nothing, Something and A lot to choose from. For the questions that correspond to 6, 7 and 8 in figure 4, participants were given the options Not at all, Somewhat, Mostly and Completely. These options were converted to a numerical system (to 0, 2 and 4 in the first instance, and 0, 2, 4 & 6 in the second) for the purpose of graphing and comparing general sentiment across the two testing sessions.

In both events, participants (on average) scored the instructor and their peers higher than the activities themselves as a support for learning. The Level 1 Learners rated the teaching instruments, instructions, activity and 'point of the exercise' somewhat higher than the Level 0 Learners. Conversely, the Level 0 Learners rated the appropriateness and enjoyment of the learning method somewhat higher than the Level 1's did.

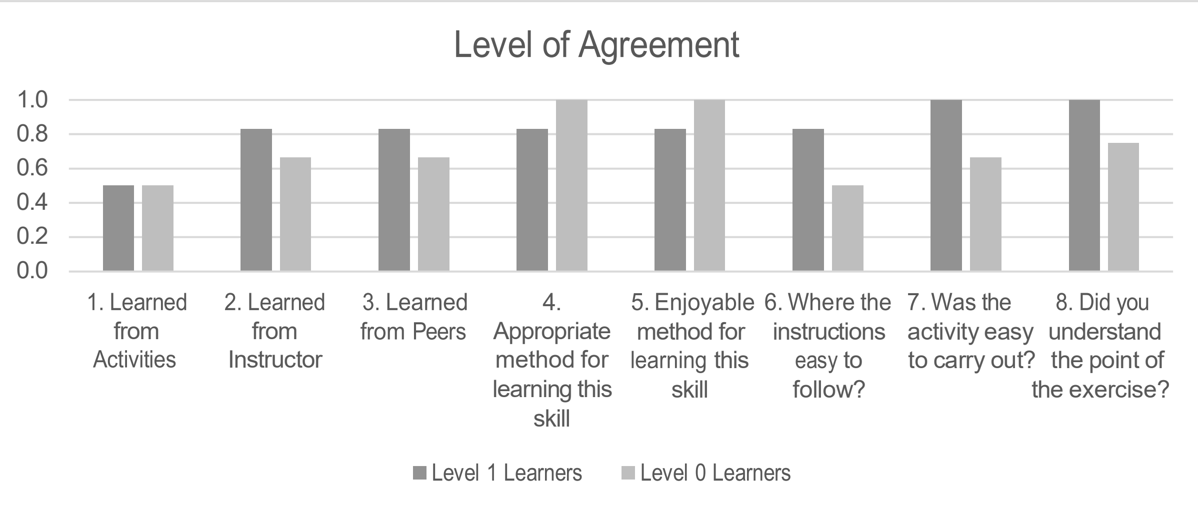

Fig. 4. Comparison of survey responses for user testing session

6 DISCUSSION & FUTURE WORK

Bearing in mind that we are discussing a handful of results across two early product testing sessions, still, there is a suggestion that these tools have different value propositions for learners at different levels of skill and knowledge acquisition.

As a teaching instrument, activities were valued less than the Instructor and Peers by both groups, indicating that learning was a social process. Further, the more experienced learners perceived the social process as being more valuable. These results are consistent with a recent case study that leveraged board games as instructional tools where the authors suggested that peer instruction may have more value among novice groups with some prior exposure (Carberry, et al. 2022).

In the next phase of this project, the team will look to explore the value of instructional board games as both an introductory tool for learners with no prior experience, and, as a revision tools for those with an elementary understanding.

ABSTRACT

This paper describes a study, with the objective of evaluating the possibilities of knowledge construction through collaborative learning (CL) in the innovative Padlet environment. During the practical classes of a math curricular unit of an engineering course, activities and assessments were carried out using Padlet. Program themes are organized by columns as a wall. Each students group accesses a problem proposal using a QR-Code. In the first part of the class, the group must solve the problem correctly, using all the materials and technologies they deem necessary. In the second part, each group will correct another group's problem. The teacher provides the necessary support with the role of advisor in carrying out the proposed problems. Through the direct observation of the teacher during CL classes using Padlet, the experiences of the authors and the evaluation of the students in these contents, it was possible to collect information that allowed demonstrating that the students developed capacities and reached competences, some of them specific to professionals in the area of this course. Students' opinion gathered with a questionnaire will also be very important data to be presented regarding their interest in this collaborative activity. In conclusion, this paper will describe, analyse, and discuss the interest in using a CL environment for the development of knowledge and for student motivation in teaching/learning math for engineers. Students' perspectives will be observed regarding their motivation and interest, allowing teachers to expand the range of perspectives on the contents covered and enriching the necessary discussions for future activities development.

1 INTRODUCTION

Facing the new society based on the creation, publication and sharing of information in a network, digital tools can and should be used as essential and complementary resources in the teaching and learning process. National and international research has pointed to collaborative learning (CL) as a facilitator in the teaching and learning process. CL is a teaching-learning methodology where students work together in groups or individually on a collective task. It could be a group activity where subjects undertake different parts of the task but contribute to a common goal, or it could be a shared task where students work together. Collaborative schools are generally successful in dealing with difficulties (students with and without disabilities must work together and support each other in building effective schools), are schools with lower dropout and repetition rates, and teachers seem to be more satisfied and committed to the work they develop [1–4].

Mathematical Analysis (MA) is usually taught in the first years of engineering courses. This curricular unit (CU) has a large number of failures and evasions due to the students' learning difficulties and the bases they bring from secondary school. It is up to the teacher to motivate his students, encouraging them to reflect and understand the proposed contents and to be aware of the importance of learning in their lives.

Padlet [5] is a collaborative platform, like a dynamic wall in a virtual panel format, where users can publish texts, photos, links, videos or any other content of interest. The Padlet also allows you to deepen your knowledge on the subjects addressed, record learning and reflections, stimulate curiosity, share with other users, that is, develop more active skills. Therefore, this tool is an important didactic resource [6, 7] that provides new pedagogical strategies, streamlining learning and allowing the teacher conditions to stimulate students' interest, which can be successfully used in the classroom. In addition, it ensures that the teacher is a facilitator of the teaching and learning process, while the student, the protagonist of this process, exercises his autonomy and creativity by translating his results into knowledge [8, 9]. Thus, the objective of this study is to discuss the potential of using Padlet as a CL environment, diversifying activities and enriching classes, capturing the active participation of students both in the classroom and outside of it, in addition to stimulating their critical thinking. How can the use of Padlet contribute to student learning? Can collaborative classes in virtual and controlled environments be useful for student success today? Are teachers, as tutors, capable of transmitting the mathematical knowledge and skills required of engineering students? These and other issues will be addressed and discussed throughout the experiments described in this paper.

2 METHODOLOGY

In the second semester of the academic year 2022/2023, in the CU of Mathematical Analysis of the Degree in Electrotechnical and Computer Engineering at the Polytechnic Institute of Coimbra, in laboratory practical classes, collaborative learning tasks were implemented using the Padlet. The classes were planned in such a way that the tasks were conceived with the intention of encouraging the active participation of the students, as well as developing skills intrinsic to the function of a researcher, assuming that they could be co-builders of their knowledge itself. Learning was focused on the acquisition of syllabus contents prescribed in the subject's syllabus, arousing interest in the contents to be explored.

3 EXPERIMENTS IN CLASSES

In the first classes, the students created the groups, registered in the Padlet and for each of the groups a column was allocated in the Padlet environment. In this column, the elements of the group were identified by their names and student numbers (see figure 1). Some experiments were also carried out in order to make the students feel comfortable using the Padlet.

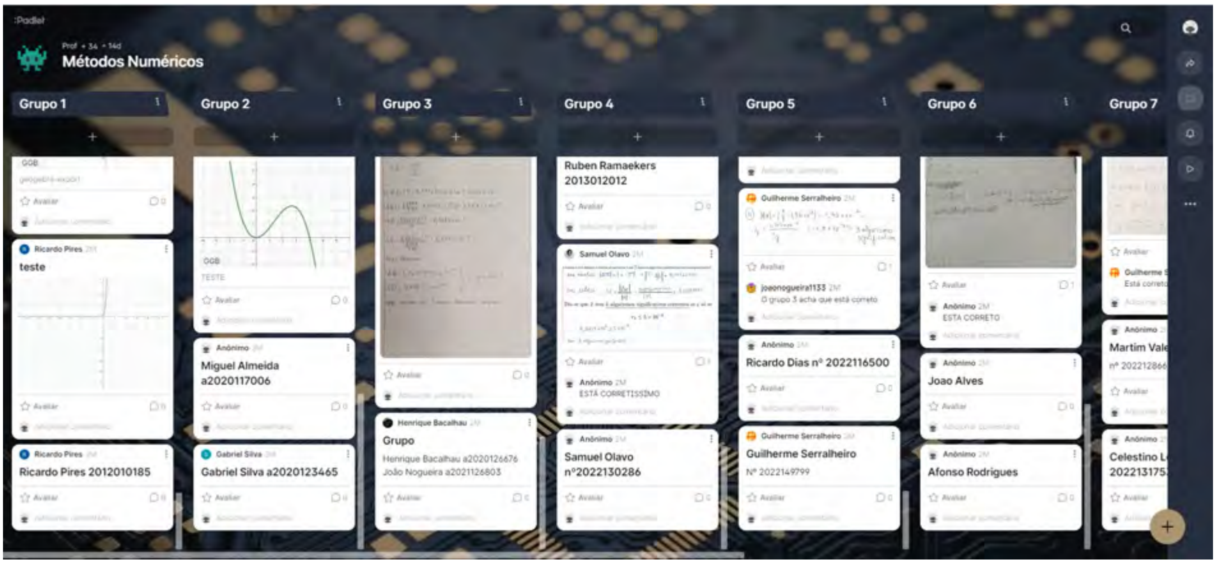

Figure 1: Example of Padlet at the beginning of laboratory classes.

In the following classes, the CU syllabus related to numerical methods were taught in these laboratory classes for 1h30m per week, where students have access to computers. In each practical class, a topic, among the existent 7, as shown in Table 1. Each task is previously planned by the teacher, following the objectives so that learning is achieved by the students. For example, in topic 1 on absolute and relative error, it is intended that students know how to calculate each of these errors and are able to have an idea of how the approximation should be so that the error has a given degree of precision. Thus, in this topic, the problem proposed to the students is based on the calculation of the absolute and relative error when approaching two values and the number of significant figures and decimal places obtained with this approximation. To access the proposed problem, the group must read the QR-code provided.

In the figure 2 it is possible to observe the posts of several groups on the topic "Graphical method for finding roots of nonlinear equations" of the third task (see Table 1). It can be observed that some of the groups solve the problem on paper and then photograph and upload the image, as in the case of group 3 and 5, others use digitizing tables, create a pdf and upload. Whenever possible, they use GeoGebra and/or other computer programs to graphically represent the functions, as can be seen in the images represented in groups 4, 6 and 7 (columns 3, 5 and 6 of figure 2 respectively).

Each practical class referring to a topic was divided into 3 parts, as shown in figure 3. Part 1, lasting 15 minutes, consisted of the individual resolution of an exercise on the topic learned in the previous class. Each exercise was quoted at 0.57% of the CU assessment mark. In part 2 of the class lasting 1 hour, students in groups of 2, independently research and learn the topic, with the guidance of the teacher.They discuss, in pairs and solve 1 or 2 random problems from a proposed list that they can access by reading the QR-code. The resolution is carried out with all the technologies they have available, such as the calculator, online applications such as WolframAlpha, Math Solver or GeoGebra and other applications that they have either on their computer or on their mobile phone. At this point they sometimes use digitizing tables, or paper and pen to register their resolution. At the end of solving the problem, they upload them to the Padlet in the column corresponding to their group.

Table 1: Topics, questions and objectives of tasks performed in laboratory classes.

Tasks	Details	
1^{st}	Topic	Absolut and Relative Error: Definition, Formula
	Questions	Calculate the absolute and relative error when approximating two values. How many significant figures and decimal places does this approximation have?
	Objective	To know the meaning of absolute and relative error and identify a certain degree of accuracy.
2^{nd}	Topic	Approximation by Differentials.
	Questions	Approximate the value of a function near a known value by differentials.
	Objective	To calculate the differential of a function and use differentials to approximate values for expressions.
3^{rd}	Topic	Graphical method for finding roots of nonlinear equations.
	Questions	Identify intervals that contain the roots of nonlinear equations through the graphical method and ensure the existence of a single root in an interval.
	Objective	To apply the graphical method and find intervals that contain only a single root of the equation.
4^{th}	Topic	Bisection Method: Definition, algorithm, and error.
	Questions	Approximate a root of a nonlinear equation using the bisection method with a given error.
	Objective	To know how to apply the procedure of the bisection method, identify its advantages and disadvantages, and calculate the error approximation.
5^{th}	Topic	Newton-Raphson Method: Definition, algorithm, and error.
	Questions	Approximate a root of a nonlinear equation using the Newton -Raphson method with a given error.
	Objective	To know how to apply the procedure of the Newton-Raphson method, identify its advantages and disadvantages, and calculate the error approximation.
6^{th}	Topic	Numerical integration: Trapezoidal Rule.
	Questions	Estimate the number of intervals in the approximation for a given error and then find the approximation by the trapezoidal rule.
	Objective	To identify when it is necessary to apply numerical integration, find the smallest number of intervals to obtain a given approximation and apply the trapezoidal rule.
7^{th}	Topic	Numerical integration: Simpson Rule.
	Questions	Estimate the number of intervals in the approximation for a given error and then find the approximation by the Simpson rule.
	Objective	To identify when it is necessary to apply numerical integration, find the smallest number of intervals to obtain a given approximation and apply the Simpson rule.

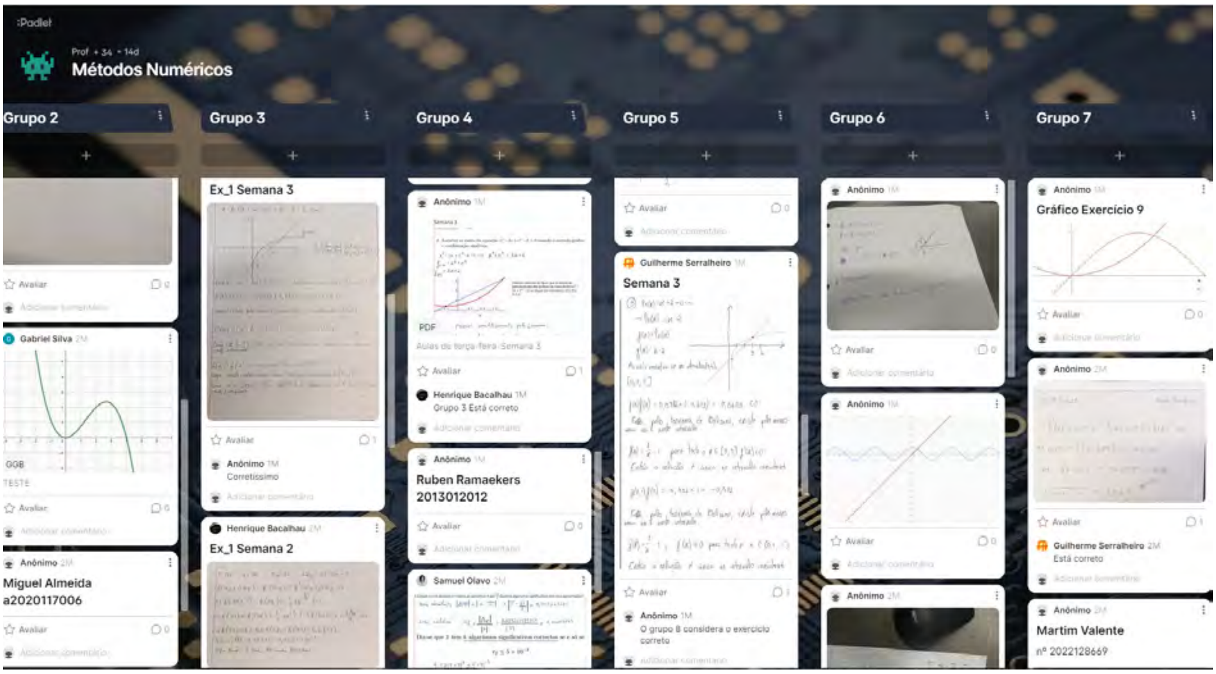

Figure 2: Example of Padle in the lesson of task 3.

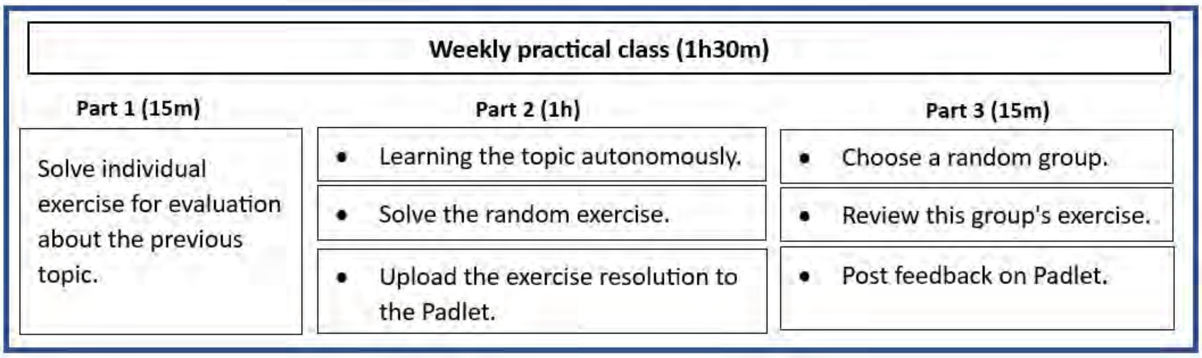

Figure 3: Flowchart of laboratory classes in each week.

Finally, in part 3 of the class lasting 15 minutes, each group chooses a partner group at random and corrects the problem posted on the Padlet, adding comments and new resolutions if necessary. In the figure 4, two feedbacks on the resolution of the problem on the topic are represented. On the left, the feedback from group 5 that corrected the problem of task 4 performed by group 3 and commented: "Group 5 considers the problem correct"; on the right, group 2 corrects the problem on task 1 performed by group 4 and comments: "Correct".

All proposed exercises and theirs corrections are available on Padlet during the semester. Students can and should refer to these resolutions while they prepare themselves for the following week written assessment exercise.

During laboratory classes (figure 3), the teacher participates as a mediator, facilitating the teaching-learning process and contributing to positive transformations in the development process of his students. He has the role of challenging, arousing curiosity and encouraging the use of his students' imagination through situations in which the student is challenged and manages to develop critical sense and logical reasoning. At the same time, he must guide the learning of each student so that at each completed stage, the student's improvement becomes continuous, and the construction of skills and competencies takes place.

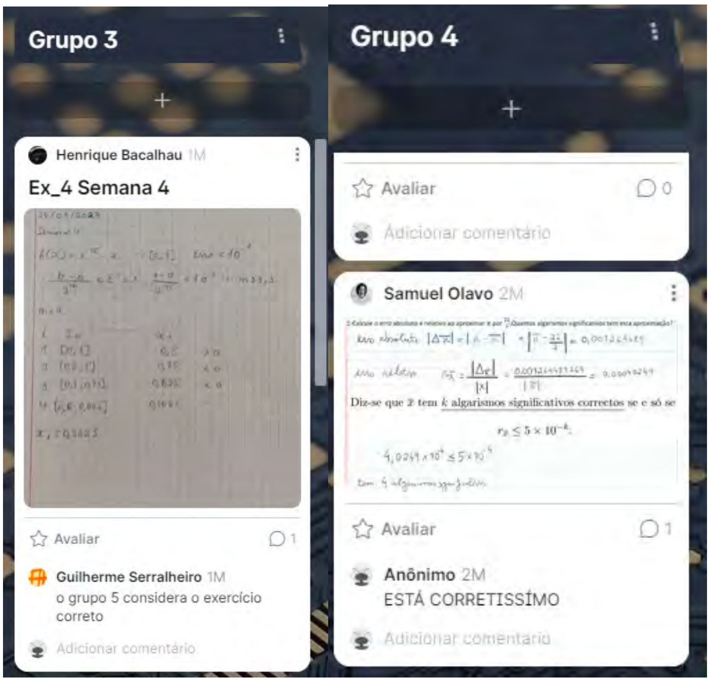

Figure 4: Exercise correction by peers group.

4 RESULTS & DISCUSSIONS

Of the 20 students who attended the laboratory classes, about 60% of the students had already carried out collaborative activities in the classroom, since many of these students had already attended this CU in the first semester. However, they had never used Padlet as a collaborative tool. In fact, only 1 student refers to having already used the Padlet, but not in a teaching-learning context.

From direct observation as an assessment tool [10], the teacher in the classroom observes the natural learning environment and collects "live" information, thus allowing momentary feedback and identifying perceptions by means of other assessment methods [11], according to the diagram shown in the figure 5.

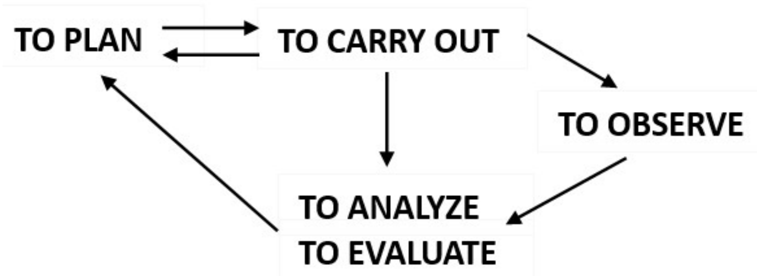

Figure 5: Classroom observation by each teacher (adapted from [12]).

During the several weeks of laboratory classes, the teacher registered the behavior of the students, both in terms of learning and in terms of collaborative activity in the group. Initially, the students were a little lost, as they did not know Padlet, nor were they used to attending math classes with access to different technologies. Regarding collaborative work, they were already used to experiences of this type carried out in the CU of the 1st semester, so cooperation and dialogue between peers was natural. As the weeks progressed, enthusiasm increased, carrying out tasks became easier, as students began to better understand how they should carry out autonomous study by the group, and the taste for the tasks grew. The peer assessment was the task that the students liked the most, because at that moment, in addition to learning being carried out, it is a way for the student to recognize the skills and competencies that he has acquired, in an autonomous way. As a teacher, it is a pleasure to observe the progress that students have obtained in mastering the contents and the joy they show, which can be observed in the evaluation of the proposed exercises at the beginning of each class.

Regarding the evaluation carried out weekly at the beginning of the laboratory classes, it was possible to verify that all students were able to acquire knowledge, although in some tasks 1 to 2 students did not have a positive grade. It should be noted that these cases of failure always involved different students. Figure 6 represents the scores, with a maximum of 10 values, obtained by students in task 1 (left) and 4 (right) carried out in week 2 and 5 respectively. From the analysis of these examples, it is verified that 89% of the students in task 1 and task 4 have a positive grade, only 11% of the students did not reach the intended results. However, 73% (task 1) and 55% (task 4) have grades equal to or greater than 8 out of 10, which demonstrates that the vast majority of students manage to acquire the skills and abilities necessary for their learning. In the remaining tasks the results are quite similar. There is always a group of students, quite small (about 2 students out of 20), who cannot reach the necessary knowledge, however we can conclude that the learning was effective and real.

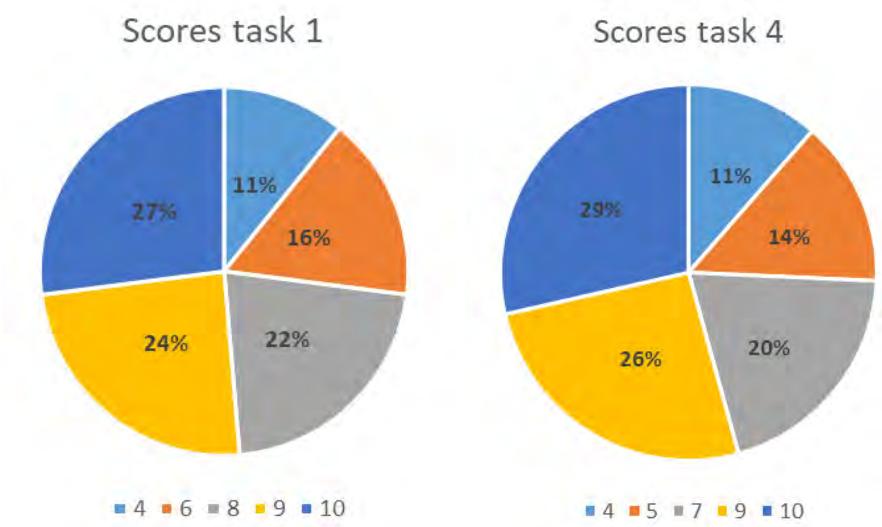

Figure 6: Student scores on task 1 (left) and 4 (right). Maximum value of the task 10 values.

5 CONCLUSIONS

The teaching of mathematics in an engineering school must capture the student's attention, be motivating, and allow students to acquire different skills and competencies that respond to the demands of the job market. Methodologies based on CL are an interesting example of how students can learn autonomously and acquired many transversal skills that will be useful to them as people and as professionals. The Padlet is a work tool that allows dynamic collaborative learning and can be used in a classroom environment in teaching-learning experiences.

In the study presented here, it was demonstrated that CL is effective learning as long as the student is involved in the constant search for his knowledge. For this reason, the presentation and monitoring of tasks in the classroom must always be accompanied and guided. The student learns to learn with his partner and together they obtain the necessary knowledge and associated skills. The teacher registers and guides, if necessary, but above all he is happy with the experience that he shows in the classroom. The use of Padlet in the CL of mathematics in an engineering course was an enriching, engaging experience that will be repeated in the next school year. The mural is a space for sharing the productions carried out by each group, where students have the resolutions of the proposed problem available at any time. The information available on this wall is extremely important for students in their preparation for the following week's assessment. This was one of the interesting aspects of Padlet recognized by the teacher and the students. Another no less important aspect was the possibility of using the Padlet to stimulate learning through the correction of problem performed by peers. By reviewing another group's problem, students are able to improve their skills and trust in their learning, fostering effective and meaningful learning, with consolidated knowledge.

The pedagogical use of the Padlet, as a technological tool, proved to be fundamental to implement CL and to experience the acquired knowledge in a more productive and relevant environment for the students' academic performance. The results show that it is possible to promote the development of students' mathematical skills and competencies, and to stimulate critical thinking, at the same time, using technology as an ally throughout the teaching-learning process.

***Conference track**: Embedding Sustainability and Ethics in the Curriculum*

***Keywords**: Sustainability, Climate change, Curriculum, Accreditation*

Professional accreditation agencies are increasing requirements on sustainability in engineering education as a response to ethical obligations, industry needs and emerging academic best practice. In 2021, Engineers Ireland increased sustainability requirements in new accreditation criteria. This paper reports on a thematic analysis carried out by Engineers Ireland on the self-assessment and achievement of these new accreditation criteria on sustainability. The analysis was conducted on the self-assessment reports from a large Irish University, referred to as University A hereafter. The results indicate that, for the purpose of meeting accreditation requirements, University A has interpreted sustainability in their programmes as either meeting the UN Sustainability Goals (SDG’s) by mapping modules to the SDG's, or by aligning Programme Area (PA) 7 *Sustainability* of the Engineers Ireland accreditation criteria with the Engineers Ireland Programme Outcomes (PO's). The paper outlines the main themes and approaches identified across 17 engineering programmes and presents 2 case studies of how sustainability is embedded in engineering curricula in Ireland.

1 INTRODUCTION

Engineers Ireland assess Engineering programmes in Higher Education Institutions (HEIs) in three main categories, Programme Outcomes (POs), Programme Areas (PAs) and Programme Management (PM). The assessment is outcome focussed, however professional accreditation agencies are increasing requirements on sustainability in engineering education as a response to ethical obligations, industry needs and emerging academic best practice (Beagon et al. 2021; DFHERIS 2021). In 2021, Engineers Ireland increased requirements on sustainability in their new programmatic accreditation criteria, specifically Programme Area 7 (PA7) *Sustainability,* becoming one of the first Washington Accord signatories to implement the new set of International Engineering Alliance (IEA) graduate attributes.

While there appears to be agreement on what the competences for addressing sustainability are (Wiek, Withycombe, and Redman 2011; Brundiers et al. 2021; Beagon et al. 2022) the ways and means they are adopted and embedded into engineering curricula is the subject of further investigation. Building on the work of ASTEP 2030 in identifying the ways that sustainability is embedded in engineering programmes (Kövesi et al. 2021; Beagon et al. 2022), this paper reports on a thematic analysis on the self-assessment and achievement of sustainability within the curricula of a large Irish Technological University, referred to as University A hereafter. The analysis was conducted on the self-assessment reports provided by University A seeking programmatic accreditation with Engineers Ireland. The paper outlines the main themes identified across 17 engineering programmes in 4 faculties at University A. Two case studies of exemplary programmes are also presented based on the outcome of the thematic analysis.

2 LITERATURE REVIEW

Accreditation is undertaken to ensure that education meets accepted standards and best practice and is the primary Quality Assurance (QA) process used to ensure the suitability of an educational programme as the entry route to a profession such as engineering (Augusti 2007). In Ireland, the professional accreditation of engineering programmes is undertaken by Engineers Ireland, the professional body for engineers. The Accreditation Board of Engineers Ireland is responsible for overseeing the accreditation process, making accreditation decisions, and recommending changes to the Accreditation Criteria.

Engineers Ireland's accreditation involves a periodic audit of engineering programmes by a visiting panel against the Accreditation Criteria. As the process is outcome-focused, the panel reviews a variety of evidence to ensure that graduates' attributes are consistent with the accreditation criteria. The criteria are aligned with the education standards for the professional titles of Chartered Engineer, Associate Engineer, and Engineering Technician (Conlon 2008).

The first Engineers Ireland accreditation was in 1982 (Engineers Ireland 2021) and there are currently more than 200 accredited programmes in Ireland. Extant literature demonstrates changes in accreditation criteria have an impact on engineering programme curricula. For example, ethics was introduced as a programme outcome more than 20 years ago. Subsequent research has demonstrated a less siloed and more holistic approach to ethics in engineering education (Homan 2020; Martin 2020). However, there are still different attitudes and cultural approaches taken to the technical & non-technical elements of the accreditation criteria in Irish Engineering Education (Martin 2020).

The Accreditation Criteria 2021 (Engineers Ireland 2021) is a comprehensive update on the 2014 version (Engineers Ireland 2014). A significant change in the 2021 criteria relates to a requirement to demonstrate sustainability in programme curricula. Specifically, graduates should have an understanding and appreciation of the environmental, social, and economic impacts of their judgments and to promote the principles and practices of sustainable development (Engineers Ireland 2021). Sustainability relates to the role of the engineer in society and professional conduct in terms of acting with honesty, integrity, and objectivity. Prior to the new criteria, where sustainability was addressed in engineering programmes in Ireland, it was often siloed within a single module (Homan 2020; Martin 2020).

Now, engineering education needs to be viewed in the context of the environment, to ensure that graduate engineers understands that they have responsibilities to society, the environment, and to their profession in general. It is more than a decade since Byrne and Fitzpatrick (2009) called for sustainability to become the context of engineering practice by:

" incorporating a sustainability informed ethos throughout engineering curricula" -p.1

by both professional institutions and educators. Furthermore, this should be accompanied by a commitment to the ethical usage of technology and data which is an important component of the increased use of data science, analytics, and emerging technologies (Engineers Ireland 2021). This is reflected in changing approaches to the accreditation of professional engineering programmes.

Sustainability means:

"reducing energy consumption and greenhouse emissions, to avoid depletion and degradation of natural resources, to ensure the needs of today's generations without jeopardising the needs of future generations" (Ghobakhloo et al. 2022) -p.12

However, including new technologies in the engineering programme curricula in isolation, is not sufficient. Complementary approaches such as sustainable thinking, circular intelligent products and upskilling and reskilling are also needed (Ghobakhloo et al. 2022).

At a macro policy level, it is widely recognised that the UN Sustainable Development Goals are important influences on engineering education (Kasinathan et al. 2022; Leng et al. 2022; Zeb et al. 2022). At a European level, two important strategic policy directions which are influencing the development of sustainability in engineering education are the Green and Digital transformations. The EU Green Deal (Kasinathan et al. 2022) demonstrates the necessity to transition to a more circular economy and increased reliance on sustainable resources, including energy (Xu et al. 2021). The EU digital agenda (European Commission 2015) will impact innovation and education for the next generation (Alexa, Pîslaru, and Avasilcăi 2022; Renda et al. 2022). Renda et al (2022) relates the UN SDGs to advances in engineering education in the realm of ethics and humanism. Looking to the future, engineering programmes should change their content after engagement with academic and industry (Cuckov et al. 2022).

In Ireland, research focusing on engineering accreditation (Homan 2020; Martin 2020; Chance et al. 2021; Byrne 2023; Doyle Kent 2021) demonstrates an opportunity to examine if changes made to the Engineers Ireland 2021 accreditation criteria has highlighted the sustainability activities embedded in the engineering curriculum.

3 METHODOLOGY

Seventeen programmes were assessed in the thematic analysis, these included Civil, Mechanical, Electrical, Electronic, Energy, Biomedical and Chemical Engineering programmes in University A. In Ireland, programmes are described by the National Framework of Qualifications (NFQ) as set out by Quality & Qualifications Ireland (QQI). The analysis included Higher Certificates (level 6), Ordinary Bachelor’s degrees (level 7), Honours Bachelor’s degrees (level 8) and Master’s degrees (level 9). The method used to identify themes was drawn from Braun & Clarke (Braun and Clarke 2006), who recommend conducting thematic analysis in 6 steps, which are outlined in Table 1.

Table 1. Braun & Clarke (2006) method for thematic analysis

	Step	Action	Output
1	Become familiar with the data	Read and re-read the submission documents	Preliminary ideas about codes
2	Generate initial codes	Organise data in a meaningful way	Coding of each document separately
3	Search for themes	Examine codes to see if some fit together into a theme	Codes organised into broader themes that say something specific about the research
4	Review themes	Modify and develop the preliminary themes	More organised and logical set of themes and sub-themes
5	Define themes	Identify what each theme is saying	Thematic map illustrating relationships between themes along with a narrative
6	Write-up	Compile report	Findings

The self-assessment documents were initially reviewed, and a set of search terms were selected to help identify relevant clusters of text for coding. Documents were searched for the keywords *"sustain", "green", "environmental", "SDG", "circular economy"* and *"climate"* respectively. In step 2, a set of codes were generated and are presented in Table 2.

Table 2. Codes identified in step 2 of Braun & Clarke's method

Code	Description
M-SDG	SDG's were mapped to particular modules within a programme.
M-PA/PO	PA areas were mapped to programme outcomes highlighting how Programme outcomes were mapped to Programme Area 7.
S-SP	Description of where sustainability is in the university's strategic plan.
S-RE	Description of where sustainability is in the university's regional contribution.
SCM - PO	A module specifically addressing sustainability was identified as a strong contributor to a programme outcome.
SCM - PA	A module specifically addressing sustainability was identified as a strong contributor to a programme area.

Following the identification of codes, a set of subcodes were generated, particularly to examine the codes SCM – PO, and SCM – PA. The PO's can be thought of as being divided into 4 technical outcomes, including PO1 *Knowledge & Understanding*, PO2 *Problem Analysis*, *PO3 Design* and *PO4 Investigation,* and non-technical outcomes including *PO5 Professional and Ethical Responsibilities, PO6 Teamwork & Lifelong learning, PO7 Communication* and PO8 *Management*. The PA's which emerged from the thematic analysis where PA6 *Engineering practice* and PA7

Sustainability. The summary of the subcodes considered for the thematic analysis are presented in Table 3.

Table 3. Summary of subcodes identified in stage 2 of Braun & Clarke's method

Subcode	Description
SCM - PON	A module specifically addressing sustainability was identified as a strong contributor to a programme outcome N.
SCM - PAN	A module specifically addressing sustainability was identified as a strong contributor to a programme area N.

4 RESULTS

Table 4 illustrates how each Programme's (PG's) self-assessment report compared across the various codes identified. As mentioned in the methodology section, a cluster of codes in SCM-PO and SCM-PA were identified and resulted in a set of subcodes being developed to explore these codes in more detail.

Table 4. Coding density by discipline and additionally by NFQ level

	Programme (PG)										
Code	**PG1**	**PG2**	**PG3**	**PG4**	**PG5**	**PG6**	**PG7**	**PG8**	**PG9**	**PG10**	**PG11**
M-SDG	4	2	2	1	1	1	1	3	1	1	1
M-PA/PO	0	1	1	1	1	0	0	0	0	0	0
S-SP	0	1	1	1	1	0	0	0	0	0	0
S-RE	0	1	1	1	1	0	0	0	0	0	0
SCM -PO	11	5	4	2	2	3	13	9	1	10	18
SCM -PA	10	0	0	0	0	7	16	14	6	11	21

Table 5. illustrates the breakdown of the strong contributor modules to each PO and PA identified in the self-assessment reports. These codes clustered on PO5, *Professional & Ethical responsibilities* and PA7 *Sustainability* which is unsurprising as an engineer's responsibility to protect the environment is explicitly written in the Engineers Ireland Code of Ethics (Engineers Ireland 2023). Of interest is the cluster of codes in PO3 *Design,* 12 modules identified as strong contributors to sustainability were mapped to this PO, implying that Engineering Programmes at University A use design modules to convey the importance of sustainability to students, this implication is bolstered in the case studies presented later.

Table 5. Sub-coding density by discipline

Subcode	PG1	PG2	PG3	PG4	PG5	PG6	PG7	PG8	PG9	PG10	PG11
SCM - PO1	0	0	0	0	0	0	0	0	0	1	2
SCM - PO2	0	1	1	0	0	0	2	1	0	2	2
SCM - PO3	0	0	0	1	1	1	4	1	0	2	2
SCM - PO4	0	0	0	0	0	0	0	1	0	0	5
SCM - PO5	6	4	3	1	1	2	6	3	1	4	5
SCM - PO6	2	0	0	0	0	0	0	2	0	0	1
SCM - PO7	2	0	0	0	0	0	0	1	0	0	0
SCM - PO8	1	0	0	0	0	0	1	0	0	1	1
SCM - PA2	1	0	0	0	0	0	0	0	0	0	0
SCM - PA6	1	0	0	0	0	0	0	0	0	0	0
SCM - PA7	8	0	0	0	0	7	16	14	6	11	20

4.1 Theme 1: Commitment to SDGs at a strategic level

All programmes declare commitment to the SDGs at a strategic level. An analysis using the EU KnowSDGs (https://knowsdgs.jrc.ec.europa.eu/) tool is used by programmes used to identify the key SDGs. Furthermore, all programmes include statements of support of SDGs at both departmental and faculty level.

A selection of rich data supporting theme 1:

“. . . aims to bring about a sustainable and fundamental change in behaviour and influence a best practice culture across the University, on all campuses through embracing the UN SDGs.”

“. . . committed to embracing Education for Sustainable Development as an integral element of the SDG on quality education as a key enabler of all the other SDGs”

“. . . by 2030 ensure that all learners acquire the knowledge and skills needed to promote sustainable development, including, among others, through education for sustainable development and sustainable lifestyles, human rights, gender equality, promotion of a culture of peace and nonviolence, global citizenship and appreciation of cultural diversity and of culture’s contribution to sustainable development”

4.2 Theme 2: Alignment with Programme Outcomes (POs)

Programme Outcomes are broad statements identifying learning parameters, content, and relationships between content areas. Many of the programmes under review were designed prior to the 2021 Engineers Ireland criteria, therefore it is reasonable that the SDGs were not explicitly included in the programme design process. However, there is evidence of alignment of elements of sustainability across all PO’s. This is particularly evident in relation to *PO2 Problem Analysis, PO3 Design, PO4 Investigation and PO5 Professional and Ethical Responsibilities.*

4.3 Theme 3: Alignment with new programme area of sustainability

Programme Areas are necessary to facilitate the engineering graduate's achievement of the Programme Outcomes. An example of the interpretation of Engineers Ireland PO's to PA7 extracted from a self-assessment report can be seen in Table 6.

Table 6. Example of the interpretation of EI POs to PA7

Engineers Ireland PO	Example interpretation of PA7
Knowledge and Understanding	Introduction to SDGs and relevance to engineering practice, manufactured products and project outputs
Problem Analysis	Query the sustainability of existing assumptions and processes
Design	Design for sustainability. Impact of SDGs on future design requirements
Investigation	Acknowledging complexities and looking for links and synergies in problem solutions.
Professional & Ethical Responsibilities	Consideration of relevant SDGs in educational development and professional practice.
Teamwork & Lifelong Learning	Inclusion of external factors and users in the commitment to sustainable action in engineering activities.
Communication	Promoting dialogue and negotiation across diverse groups in addressing SDGs.
Engineering Management	Involving people in joint analysis, planning and control of decisions.

5 SUMMARY AND ACKNOWLEDGMENTS

An outcome of the analysis of codes and subcodes were the identification of 3 exemplary programmes at University A in terms of how sustainability was being embedded within the taught content of the programme, an Energy programme delivered at Bachelor level and 2 Mechanical programmes delivered at Bachelor and Master level, the latter of which will be taken together.

5.1 Energy Engineering programme

In this programme, 20 codes were identified presenting modules as strong contributors to PA7 *Sustainability*. Four modules in particular, contributed 72% of this coding density. This is not a prescribed approach to addressing PA7, however the coding indicates that modules addressing PA7 were also strong contributors to PO4 *Investigation and* PO5 *Professional & Ethical Responsibilities.* Implying that sustainability is embedded in experimental design and simulation. Of particular note is the 15 ECTS work placement module, where students get first-hand experience of their professional and ethical responsibilities as part of the ten-week placement.

Typically, students undergo specific training for the company they are placed in, and this will often reinforce these responsibilities. Working under the guidance of a mentor, students get continual feedback regarding their professional performance and expectations as engineers, helping students to grow personally and professionally.

The new programme area PA7 *Sustainability,* is evidenced across all four years of the programme with a higher proportion in years 2 and 4. With respect to assessment, 77% of modules with codes contributing to sustainability in POs, are assessed fully via continuous assessment. Similarly, 75% of modules contributing to PA7 are assessed fully via continuous assessment. A first-year foundation module of particular interest related to Climate Change & Energy and contributes to PA7 as well as *PO1 Knowledge and Understanding, PO2 Problem Analysis, PO4 Investigation* and *PO7 Communication.*

5.2 Mechanical Engineering programmes

In these programmes, 16 codes were recorded relating to a module specifically addressing sustainability being identified as a strong contributor to PA7 *Sustainability*. This is not a prescribed approach to addressing PA7, however the coding indicates that modules addressing PA7 were also strong contributors to *PO2 Problem Analysis, PO3 Design, PO5 Professional & Ethical Responsibilities* and *PO8 Engineering Management* with thirteen codes identified relating to a module specifically addressing sustainability being identified as strong contributors. This suggests that while Sustainability is a Programme Area rather than a Programme Outcome, it permeates the Programme Outcomes.

Of particular note with regard to strong contributors to PA7 are the capstone design project on the Master's Programme, a 30 ECTS module in which students must consider all relevant societal impacts, including environmental impacts of their designs within the project thesis and the capstone design project on the Bachelors Programme (a 10 ECTS module where students must critically assess the project against appropriate design, safety, commercial and ethical criteria). Sustainability is evidenced across years 1,2 and 4 of the Bachelor programme with a particularly strong emphasis placed on sustainability in the Master programme, with 89% of modules contributing to sustainability being assessed through course work; including continuous assessment, lab work and reports. Only 3 modules contributing to sustainability contain a written examination and in no case is this 100% of the assessment on these modules.

5.3 Conclusions

The main findings were that University A made a strong commitment to align all programmes to the SDGs at a strategic level, embedded sustainability across multiple POs and identified strong contributor modules to *PA7 Sustainability* in a similar approach to that of the assessment of POs.

5.4 Limitations

A limitation of this study is that self-assessment reports are exactly that, self-assessed measures of achievement. In the estimation of Engineers Ireland, often individual academics underestimate their achievements in their self-assessments, and much more detail can be found in the individual evidence folders, which contain among other things, exam scripts, external examiner reports and module descriptors, as well as supporting evidence provided at accreditation visits and captured in the panel reports, which are prepared by external academics and industry representatives. There is a richness of data to explore on how sustainability is embedded in these programmes that goes far beyond the self-assessment reports that lies outside the scope of this paper.

5.6 Recommendations & future work

This paper is not conceived as a final product, but as an initial step in a wider research project. It demonstrates the accreditation process can now capture best practice examples of how sustainability is being embedded in engineering curricula across Ireland. It may be tentatively concluded that there has been an increase in awareness of the SDGs and sustainability practices in engineering education. These findings, however, do not establish a causal link between the new accreditation criteria and an increase in sustainability in engineering education. This would require a review of the self-assessment reports longitudinally to assess the relative influence of the previous Engineers Ireland criteria, as well as the mission statement of the University at the last accreditation visit. Further research is recommended, specifically in-depth interviews with accreditation panellists and the programme team would provide an understanding of the perceived gaps in the self-assessment reports, expansion of the dataset to include all HEI's who have been assessed against the 2021 accreditation criteria, and a review of the additional programme evidence provided in the submission for accreditation. These findings will be presented to the Engineers Ireland accreditation board and form part of the conversation about how the Engineers Ireland accreditation criteria are reviewed to reflect best practice in engineering education.

Conference Key Areas: *Innovative Teaching and Learning Methods*
Keywords: *Higher education, Innovation readiness, Teaching practice, Maturity Model,Challenge based learning*

ABSTRACT

Educational institutions that want to successfully innovate regarding the education they provide must synchronise organisational growth with educational growth. To support such innovation, a maturity model can help identify successful teaching and learning practices by encouraging experimentation, collaboration and alignment with strategic goals. Although maturity models that support staff in the process of innovating education are valuable, they are scarce. This phenomenological study explored the views of staff from the Centre for Expertise in Learning and Teaching (CELT) on readiness for innovation at the University of Twente (UT). We surveyed staff members who were actively involved in projects or teacher initiatives aimed at educational innovation. The questionnaire consisted of 137 closed-ended multiple-choice questions (e.g. 'Is teaching support guided by the latest research findings?') and answers on a five-point scale ('Not', 'Partly', 'Largely', 'Fully' and 'Don't know'). The survey's structure was based on that of the maturity model. The questions were divided into five categories of processes: learning (directly affecting pedagogy), development (related to the creation and maintenance of resources), support (related to support and operational management), evaluation (related to evaluation and quality control throughout its lifecycle) and organisation (related to institutional planning and management). After the survey results were analysed, respondents were invited to reflect on its outcomes, share their insights and suggest possible explanations for the results. In this paper, we present the educational support staff's maturity model results

and discuss how these results can influence the effects of teachers' innovative practices.

.

1 INTRODUCTION

1.1 Innovation in Higher Education

This study examines how an innovative educational approach maturity model can be used effectively to not only help higher education institutions (HEIs) innovate regarding their teaching practices, but also to provide a framework enabling staff professional development. This model can help staff identify areas needing improvements and provide guidance on where and how to implement improvements within an organisation's larger context to achieve maximum effect (Chapel, DePryck, and Buunk 2022). This paper presents new research data and insights which can help improve the maturity model, making it valuable to teaching staff who want to increase educational innovation. In recent years, challenges posed by rapid changes to educational approaches and the need for future-proof education have become increasingly apparent. In response, HEIs worldwide have sought to improve their teaching practices through innovation. Despite their efforts, many HEIs struggle to identify effective strategies for making these changes. This article presents the challenge-based learning (CBL) maturity model developed specifically for HEI support and teaching staff who want to innovate in education (Chan et al. 2017; Jiang et al. 2020; Snow Andrade 2020). This tool enables HEI staff to assess current innovations and identify areas for potential innovation in teaching practices. The tool can also guide teachers' development by helping them understand how the educational process contributes to educational innovation. The model focuses on the quality of five main processes essential to success: learning, development, support, evaluation, and organisation (Figure 1).

Learning	**Processess that directly iimpact the pedagogical aspect of the innovative educational approach** *This process deals with the core aspect of education, the acquisition of knowledge, skills, and attitudes. The primary focus is on innovatieve aspects of the curriculum and the desired learning outcomes*
Development	**Processess surrounding the creation and maintenance of resources for innovating education** *This process involves learning and support of the teaching staff, infrastructure, and facilities required for delivering quality education.*
Support	**Processess surrounding the support and operational management of the innovation** *This process involves the provision of support services to learners to ensure their holistic development such as health counseling and career guidance.*
Evaluation	**Processess surrounding the evaluation and quality control of the innovation** *This process involves the continuous monitoring and evaluation of the education delivery process of the innovative approach, such as curriculum evaluation, teacher evaluation, and learner assessment.*
Organisation	**Processess associated with institutional planning and management** *This process involves the management and administration of the institution such as governance, finance, and resource allocation.*

Figure 1. The five process areas that facilitate the delivery of education (Marshall, 2007).

Based on an extensive literature review, we identified the 35 sub-processes necessary for successful innovation in education, which were divided into practices. The CBL maturity model can be divided into three main levels: organisational, programme and course (Chapel and DePryck 2022).

1.2 Maturity Model to Support Innovation

HEIs are expected to deliver effective, high-quality education (Avvisati, Jacotin, en Vincent-Lancrin 2014; Biggs en Tang 2011). Their effectiveness depends not only on the quality of their teaching staff, but also on various processes that facilitate the delivery of education (Chapel et al. 2022; Marshall 2007)). By breaking down complex educational systems into related process areas that can be examined independently, staff can independently use the CBL maturity model to evaluate the effectiveness of planned innovation after readiness has been identified at the institutional level. For example, if the item ‘Teaching staff are recognised and rewarded for their engagement with innovation’ is answered on the institutional level using ‘Not’, this provides teaching staff with a valuable starting point for assessing the feasibility of their innovation ideas and informing their decisions on moving forward. Research has found that maturity models can be powerful tools for making meaningful change in education (Tocto-Cano e.a. 2020). In addition, these models encourage teachers to become more reflective practitioners by motivating them to consider the larger implications of their decisions when introducing new practices into their teaching curricula (Demir en Kocabaş 2010; Gunsberg e.a. 2018). However, despite the potential benefits, there are still challenges associated with successfully applying these models within HEIs (Eden et al. 2016).

1.3 Supporting Innovation

Because the University of Twente (UT) wants to prepare students to obtain knowledge outside their own fields of study and take into consideration the societal effects of their actions, it has for many years used a project-based education called the Twente Onderwijs Model (TOM) as the main educational approach for all bachelor’s programmes. UT has also used CBL initiatives in the past. By running CBL pilots, ECIU University[2] has played an important role in implementing CBL within UT (Chapel et al. 2022).. Thus, to identify and analyse the readiness of educational support for CBL innovation, Marshall’s e-learning Maturity Model was adjusted into a maturity model for CBL. Notably, this adjusted model is not limited to use with CBL, but can be used with any innovative approach to education.

1.4 Centre of Expertise in Learning and Teaching

The Centre for Expertise in Learning and Teaching (CELT)[3] is an academic department within UT that plays an important role in enhancing students’ educational experiences by supporting and guiding teaching staff. CELT provides teaching staff with various services, including help designing courses and modules, accreditation of programmes, professional development opportunities and new educational approaches to teaching practice. For instance, UT’s strategic plan, Shaping 2030, introduces CBL’s role in UT’s education and encourages teachers to experiment with

[2] https://www.eciu.eu/

[3] https://www.utwente.nl/en/ces/celt/

it, with the ultimate aim of positioning UT staff as pioneers in innovative education in alignment with the university's mid-term to long-term goals. As a result, CELT has incorporated CBL expertise into its support services, providing CBL training opportunities and assigning educational advisors with specialised CBL knowledge.

2 METHODOLOGY

2.1 Questionnaire

This article presents a phenomenological research study exploring the perspectives of CELT staff regarding UT's readiness for innovation. Although phenomenological research may not typically produce generalisable findings, it can provide insights that help identify and understand a particular topic (Dukes 1984; Sloan en Bowe 2014). Respondents were asked to complete a questionnaire consisting of 138 closed-ended multiple-choice questions, their answers to which indicated the extent of their agreement with a series of statements. The answer choices, based on a five-point scale, included 'Not', 'Partly', 'Largely', 'Fully' and 'Don't know'. The survey questions were categorised according to the five main areas of the CBL maturity model and did not allow for elaboration or comment. The responses were analysed to identify patterns, trends and key themes. After these were identified, the descriptive analysis of the results was shared with the respondents, who were individually asked to verbally reflect on them. Reflection prompts were used to scaffold the responses. The analysis of these results focused on identifying similarities and differences in the respondents' experiences and perceptions of the phenomenon, as well as the underlying themes or patterns reflected in audio notes of their responses

2.2 Problem Statement

The pilot test of the CBL maturity model tool made evident that there were considerable differences in the ratings provided by support staff (i.e. at the institutional level). This raised concerns about a lack of clarity or consensus regarding the support systems available to teaching staff who want to innovate their practices. This study aimed to increase the understanding of these discrepancies and the reasons behind them.

3 RESULTS

3.1 Descriptive Analysis

The CBL maturity model instrument was filled out by four CELT members who were involved in the implementation of CBL at UT (see Table 1 for their roles and years of experience).

***Table** 1. Job Function and Experience of Respondents*

Role within CELT		Experience (years)
R1	Coordinator Teacher Professional Development	25
R2	Coordinator Senior Teaching Qualification	30
R3	Challenge-based Learning Expert	10
R4	Challenge-based Learning Expert	2

Of the four, R3 and R4 were closely involved with CBL initiatives, while R1 and R2 had a more generic overview of them. The main process scale included subprocesses of the main processes that had Cronbach's alpha values $\geq$ 0.7 (75 items) (Table 2).

***Table 2.** Cronbach´s Alpha Main Processes*

	Cronbach´s Alpha	N	M	SD
Development	0.984	37	41.5	31.0
Learning	0.895	8	12.3	5.9
Support	0.943	10	14.5	8.7
Evaluation	0.957	13	13.8	12.3
Organisation	0.917	7	6.0	5.8

The option 'Don't know' was the one most selected by respondents, followed by 'Not', and together these two accounted for more than 50% of the responses for each process. As Figure 2 shows, when the responses 'Don't know' and 'Not' were combined, there was a significant difference between R1, R2 and R3 on one hand and R4 on the other.

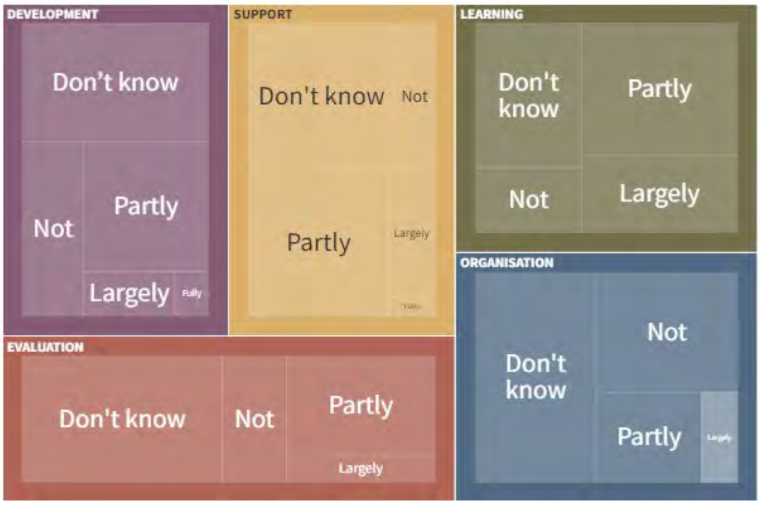

Figure 2. Ratio of answer options.

Most 'Don't know' and 'Not' items were related to finance or policy. Figure 3 shows four items, which were scored as R1, R2 and R3 = 'Don't know' and R4 = 'Not'.

***Figure 3**. Items related to the process organisation: above-average answer 'Don't know'.*

1. *Information on the effectiveness of design and development support guides the strategic and operational planning of CBL.*
2. *The effect of design and development support guides the allocation of resources for support. '*
3. *Information from CBL reviews guides CBL initiative planning.*
4. *Risk assessments of failed CBL initiatives are formally reviewed to identify factors to include in the risk analysis and mitigation plans of existing and future CBL initiatives.*

Figure 4 shows items that the respondents seemed to agree on and for which the results showed an above-average readiness (R1, R2 and R3 = 'Partly' and R4 = 'Largely') and that mainly questioned the pedagogical support and resources available to the teaching staff.

1. *Teaching staff are provided with information on how CBL pedagogy support a range of student cognitive outcomes.*
2. *CBL design and (re)development procedures include assistance for teaching staff in changing pedagogies.*
3. *Teaching staff are provided with support resources (including training, guidelines, and examples) on how to assist students in developing skills.*

Figure 4. Items with above-average readiness.

3.2 Respondents' Reflections

In their verbal reflections, the respondents were asked to provide insights into the trends of the analysis. R1 and R3 submitted their reflections, which showed that support for CBL was just beginning when the surveys were completed and the educational approach was relatively new to HEI. They noted that a lack of both knowledge of the approach and visibility of available support structures contributed to the high rate of 'Don't know' responses. R1 explained that while support was available, it was not centralised, and information was not readily available. R3 confirmed that support was not visible and information not structured. Thus, the respondents stressed the need to rethink the way in which innovation support is provided, including the professionalisation of the support staff itself and the acquisition of knowledge to address the complexity of education. Furthermore, R1 noted that the 'Don't know' and 'Not' answers were guided by a lack of both awareness of policy developments and a clear vision regarding educational innovation. According to R1, support would have been more systematic and clearly organised if there had been better understanding of who had the power to make decisions. In addition, R3 reflected on the message that CELT conveys when it presents support staff as advisers: "*As an advisor, you tell [teachers] what to do, but they don't need advice, they need someone who stands beside them*'. R3 suggested that teachers must be more engaged and encouraged to drive innovation themselves while having the ability to access continuous hands-on support for innovating their practices. Lastly, R1 expressed the belief that CELT plays a critical role in providing inspiration, co-creation and feedback that promotes evidence-informed educational innovation. R1 emphasised that the support department should be involved in policy development and defining a clear university-wide vision to guide support offerings.

CONCLUSION

This paper provides a comprehensive analysis of the responses from educational support staff at UT, using the CBL maturity model instrument, to assess UT's institutional readiness for educational innovation. It also examines the current manifestation of support structures within the institution and discusses potential improvements for more effective scaffolding of educational innovation.This study highlighted a significant challenge faced by support structures when introducing educational innovation approaches like CBL into higher education practices - a lack of awareness and visibility. To address this issue, several key recommendations are proposed.Firstly, it is crucial to allocate sufficient time and opportunities for educational support staff to acquire the necessary knowledge and skills to navigate the complexities associated with introducing new elements into education. Continuous professional development should be prioritized to ensure support staff are equipped to effectively support educational innovation.Secondly, establishing a clear connection between the educational support department and university policymakers can lead to a more systematic and organized support structure. Such a connection would enhance the effectiveness and success of educational innovation initiatives by aligning the support provided with the strategic goals and vision of the university.Lastly, educational support staff must assume a crucial responsibility for promoting evidence-based educational innovation. They should actively participate in the development of policies and collaborate with stakeholders to define a shared vision that guides the university's support services. By doing so, support staff can provide inspiration, engage in co-creation, and offer valuable feedback, ultimately fostering a culture of evidence-based educational innovation.Implementing these recommendations will lead to improved support structures and enhance the effects of educational innovation on teaching staff. By providing a strong foundation of support, universities can effectively facilitate teaching staff in their pursuit of innovative practices.

ABSTRACT

Iron Range Engineering is an innovative learning program using project-based and work-based pedagogies. The Bell Academy (BA) is a semester-long bridge experience between the first two years of STEM foundation and the final two years spent in full-time industry co-op placements. The curriculum within the academy is delivered within three domains: technical, design, and professional. The transformation to thriving as a student engineer in an industry placement is intentionally embedded in each stage of the program as students develop higher levels of self-awareness, professional responsibility, and self-directedness.

Students not only gain technical engineering knowledge, but also apply that knowledge within team-based, ill-structured design projects, acting as engineering consultants to industry clients. Technical learning is delivered in one-credit modules, which supports both the development of the individual as a student engineer and the execution of the project. Professional competencies are learned in-situ as teams encounter natural struggles. Development is supported through workshops, which cover topics such as conflict management, leadership, technical writing, data science, public speaking, inclusive action, etc. Through iterative assignments and practice, such as resume development, negotiation, and interviewing, students develop a skills portfolio to identify and acquire a position to begin and maintain their career.

Through more than a decade of implementation, several unique learning strategies have been developed and refined. The paper will briefly describe the model used and provide the strategies as potential tools for adaptation and implementation in engineering programs worldwide.

1 INTRODUCTION

Throughout its history, engineering education has seen periods of innovation and growth in the education and identity development of future engineers. The past quarter century is a period where scholarly activities and research from around the globe have called for an unprecedented need for the evolution of engineering education so that graduates meet the needs of a society that is experiencing an accelerated rate of change (Sorby and Fortenberry 2021).

Iron Range Engineering (IRE) began in 2009 as a regionally-based, project-based learning (PBL) upper-division (i.e., last two years of bachelor's degree) program based on the Aalborg University PBL model (Kolmos, Fink, and Krogh 2007). Students completed their lower-division (i.e., first two years) requirements (i.e., calculus, physics, chemistry, general education, and foundational engineering skills) at a regional community college. At the time, PBL was not common in the United States and was initially met with pessimism by higher education peers and some in industry. Over the next decade, PBL became much more accepted and desired. Recognition grew with IRE being awarded an ABET Innovation Award in 2017 and Ruth Graham’s MIT commissioned report identifying IRE as one the current and emerging world leaders in this transformation of engineering education in 2018 because of its exploration and innovation (Graham 2018; Ulseth 2016; Johnson and Ulseth 2016). It was also clear that future innovation was needed to both further develop the PBL curriculum and grow the number of students who could be served by the model.

In August 2019, after some initial small-scale piloting, 20 students from community colleges across the United States formed the program's first cohort for a co-op work-based learning model adapted from the Charles Sturt Engineering program (Morgan et al. 2021). Upon completion of their community college program, student engineers enter the BA for one semester followed by 24 months of paid co-op in industry, culminating in graduation with a Bachelor of Science in Engineering (Johnson, Ulseth, and Wang 2018).

The BA is a primarily in-person, intensive semester-long experience providing students with a convergent, transformative experience from their prior life and education experiences to meet their developmental needs for success in a four-semester co-op placement. The academy explicitly focuses on developing student technical, professional, and design competencies, along with attainment of the co-op learning experience and the building of strong social connections. Students are also encouraged to seek out and create value in their learning experiences.

The outcomes of the BA (Ulseth, Johnson, and Kennedy 2021), include:

- Gaining the knowledge and skills necessary to find, interview for, and acquire co-op positions.
- Learning and implementing an engineering design process while completing a design project for an industry client.
- Preparing professionally to thrive as contributors on engineering teams while on co-op placement.
- Developing self-directed learning (SDL) capabilities as technical learners as they advance their acquisition of core technical knowledge and prepare to undertake advanced, student-led technical coursework.

This paper aims to show the theoretical and practical basis of how IRE helps students achieve these outcomes by the end of the academy, adequately preparing them for their first industry co-op placement through design, professional, and technical learning.

2 RESEARCH BASIS

Four key themes for transforming engineering education manifested themselves in the first 9 years of development and implementation of the original IRE model (Johnson, Ulseth, and Raich 2022), which would be used in the next innovation of the curriculum. **Authenticity** is a necessary component of the learning experience. Student motivation is optimized when they feel they are doing authentic work that has value and impact. The **curriculum must reflect the desired outcomes**. Important aspects which explicitly foster student development of desired outcomes for the educational model must be purposefully built into the curriculum. In this model, the development of technical, professional, and design competencies are highly and equally valued. **Strong social connections** are necessary and thus relationships between faculty-to-students and student-to-student must be purposefully cultivated. Physical spaces and a culture of trust, joy, collaboration, openness, purposeful inclusiveness, and courage empower relationship building and the development of a common set of professional goals. Transformative educational models are built through scaffolding of an **entrepreneurial mindset**. An entrepreneurial mindset with a purposeful approach to continuous improvement is necessary to not only keep the curricular innovation alive, but to also ensure the educational model and program stays ever relevant and of value for both the students and the communities served during this period of rapid change in the world.

Each of these four themes emerged within study of the IRE program, but they ultimately align with the widely researched and implemented Universal Design for Learning (UDL), a research-based framework for supporting the teaching and learning for all people. Therefore, this paper frames the practices of the BA through the lens of the UDL framework. The UDL framework (Rose 2000) consists of three main principles that are based on research in the learning sciences and cognitive neuroscience. The first principle is providing **multiple means of engagement** (the "why" of learning), and its guidelines support development of the affective network of the brain, resulting in learners that are purposeful and motivated. The second principle is **providing multiple means of representation** (the "what" of learning), and its guidelines support the recognition networks of the brain to develop learners that are resourceful and knowledgeable. The third principle is **providing multiple means of action and expression** (the "how" of learning), and its guidelines support the strategic networks of the brain and develop learners that are strategic and goal directed.

3 METHODOLOGY

As the only undergraduate engineering bridge program of this caliber, a deeper dive into the framework and practices was warranted. This study was performed by the authors as a research team, which consisted of two program directors, two tenure-track faculty members, and a partner community college administrator.

After reflecting on the unique processes and practices utilized within the BA and researching UDL principles, the research team recognized an opportunity to align theory and practice with the goal of supporting other bridge programs and educational experiences. To support this dissemination, an analysis of the practices of the BA was performed using each of the three principles of UDL – the "why", the "what", and the "how". UDL offers a variety of best practices in each of these areas; a list of best practices is shown in Fig. 1. While these best practices only include a portion of those suggested by the overall UDL framework, the research team worked together to highlight those intentionally implemented and aligned with practices in the BA.

Results will be reported in the form of recommendations for implementation. The recommendations were developed by the research team after the individual sections of the "why", "what", and "how" were developed, leading to overarching themes and high-impact practices to be highlighted. Because not all programs have the ability to overhaul an entire program or start a new program, the recommendations are designed to be approachable, regardless of the context.

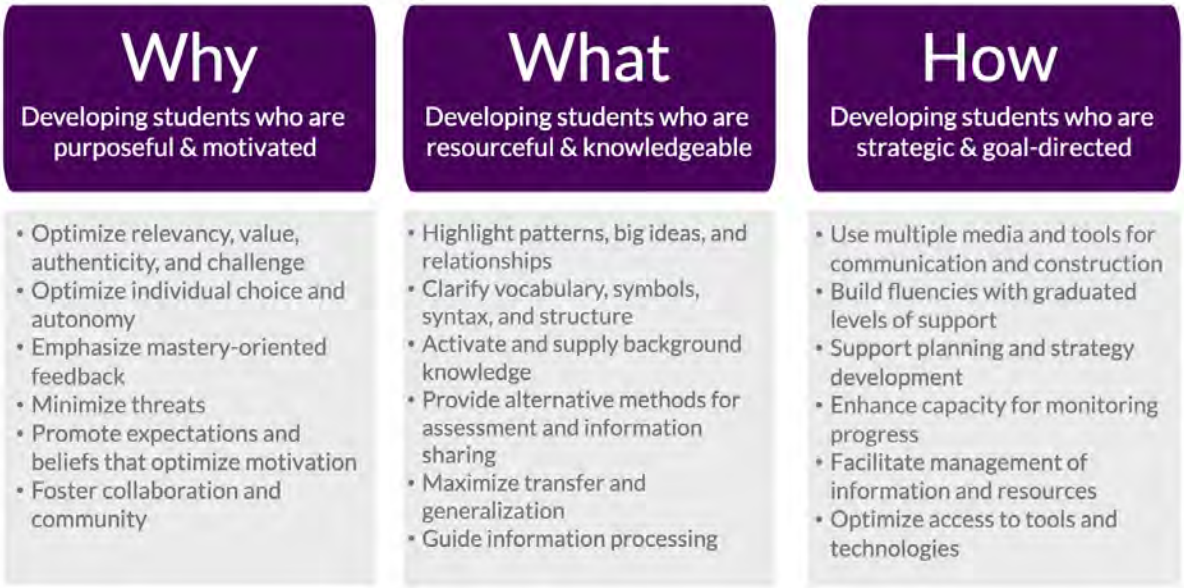

Fig. 1. A list of Universal Design for Learning best practices that are integrated in the BA. Adapted from CAST (CAST 2018).

4 THE "WHY"

The evidence presented in this section supports the design and implementation of the academy with the overall goal of "the why" being the development of expert learners who are purposeful and motivated. Intentionally creating that space allows the foundation to be built of students' interest, effort, persistence, and self-regulation within their engineering education through those best practices highlighted within the "Why" in Fig. *1*.

The BA curriculum is designed to maximize and promote student motivation to learn, be authentic, and be challenged (Ulseth 2016). Ryan and Deci's self-determination theory (SDT) serves as the foundation for empowering motivation with autonomy, competence, and social connectedness as the triad of basic human needs that when optimized, maximize motivation (Ryan and Deci 2000). During the BA, students are given choice and ownership to promote autonomy through means such as performing authentic deep learning activities in technical competencies that are challenging without seeming impossible, choosing a topic of choice for presentations and discussions, designing their path and engineering focus area through courses taken, and others. From the beginning of the BA, students are immersed in developing their understanding of and skill in executing SDL (Ulseth and Johnson 2017) through personal self-assessments and learning journals, requiring reflection.

Each student that enters the academy is part of a cohort who will navigate their path through the 2.5 year program together. Learning in the academy often takes place in small, collaborative teams within all three aspects of student learning (i.e., design, professional, technical). This ensures that student engineers are capable of working on productive cross-functional teams when they arrive at their engineering co-ops (Davis and Ulseth 2013). Teamwork is included in design projects, in classroom activities, and with all faculty and staff members. High levels of community and collaboration are also encouraged through regularly scheduled student-life events, with faculty and staff also involved, so students are involved with one another outside of the classroom, normalizing the ability for open communication with all.

Mastery-oriented feedback using a scale focused on a helix of continuous improvement is central to the learner-teacher relationship (Singelmann, Wang, and Christensen 2023; Christensen et al. 2023). This feedback is based on a 5-Point grading scale, detailed in Singelmann et al. (Singelmann, Wang, and Christensen 2023), taking the focus away from a traditional grades-based outcome focus to a growth-mindset focus (Dweck 2007). While student engineers receive developmental feedback from their professors, they also are scaffolded to develop high levels of self-assessment capability through technical reflections weekly and across all courses (Johnson and Ulseth 2016). Metacognition supports self-assessment and SDL processes. One example of this is that students write a metacognitive memo inspired by Tarricone's Taxonomy of Metacognition (Tarricone 2011).

Throughout the academy, it is expected that students learn and practice the professional conduct necessary for future placements in industry. There are daily check-ins scheduled each morning to practice consistent messaging across multiple domains, such as scheduling, time management, identity development, technical writing skills, data science tidbits, etc. that *consistently* convey these expectations and the beliefs needed to support the students in their growth.

The program overall aims to minimize threats, creating safe space to make mistakes in this learning process. This is done through iterative, low-stakes opportunities to practice and develop professional competencies and identity. A strong example of the minimization of threats is that while IRE does not place students in their industry positions, scaffolding is provided to help students acquire those positions. By holding iterative assignments and practice that are built into the curriculum, students develop a skills portfolio to identify and acquire a position to begin and maintain their career. These assignments and practice include activities such as career development specific workshop engagement, resume development, negotiation practice, and mock interviewing. Because of the success of IRE students at industry placements in the past, IRE can hold their own career fairs, both on-site and virtually, to further support students in successfully navigating their transition to full-time engineering.

5 THE "WHAT"

To successfully prepare students in all three curricular domains in the BA, students have many opportunities to receive information and apply it. The technical, design, and professionalism learning spaces promote development of students who are resourceful and knowledgeable through the best practices highlighted within the "What" in Fig. *1*.

All technical learning in the BA is delivered in one-credit modules. Through formatting each engineering competency (e.g., Thermodynamics, Electronics, AC Circuits, Statistics, etc.) as one-credit versus a traditional three-credit format, students can activate their prior learning and build upon it to supply additional background information to support the application to design projects and ultimately their industry placements. All one-credit modules are focused on two to six fundamental principles (FPs), which highlight the patterns, critical features, big ideas, and relationships behind a given topic. Instead of trying to teach students everything, the goal is to teach them enough to be confident in the FPs, in calculation, application, and communication. This is supported by clarifying key vocabulary, symbols, syntax, and structure for each of the fundamental principles. Students are also held accountable for continuing to activate their background knowledge about the fundamental principles in future courses, as well as in their design projects and industry placements. To allow for alternative methods for information sharing, the assessment of technical learning is offered in multiple ways (e.g., oral exams [Christensen et al. 2023], low-stakes quizzes, deep-learning activities, etc.).

Students are also able to apply and develop their engineering learning through ill-structured design projects. During the BA, students work in teams of four to five as engineering consultants with industry clients. An IRE staff member also serves as a facilitator with the project to assure that relations and quality of work are as expected. Through these design projects, students can maximize their transfer of technical knowledge to new contexts. Some technical information they may already be familiar with to generalize to the project, but other types of information may have to be obtained through SDL methods, requiring students to focus on how to embed new ideas into their current understanding. Students have one hour of training each week on the principles and practices of SDL to support them in their design work.

Within the BA, many professional competencies are learned in-situ as teams encounter natural struggles. Development is supported and scaffolded through workshops, which cover a variety of topics (e.g., conflict management, leadership, technical writing, data science, public speaking, modern tools, inclusive action, etc.). These workshops come in two forms: 1 to 1.5 hour long workshops that happen individually or 15 minute workshops every week of the BA for 16 weeks. Some of the topics are covered every BA as they have been important to each set of students, but some topics have evolved over time on a needs-basis and perceived from student outcomes and feedback. Because of their current work on engineering design teams, students are able to transfer and apply their workshop learning to situations in real-time. Rather than leaving professional development up to chance, these workshops guide information processing by creating time and space for students to intentionally practice and reflect on development of professional skills.

6 THE “HOW”

The BA is designed to support development of students who are strategic and goal-directed through the best practices highlighted within the “How” in Fig. *1*.

The BA is delivered to emulate industry structure to prepare student engineers to thrive as working engineers, which in the two years after BA, will also include being full-time students. Students are expected to work on their design, professional, and technical learning for ~40 hours each week for 16 weeks, which takes place during the hours of about 8 am to 4 pm each day and are structured to allow instructors to make sure students have access to information, resources, tools, and technologies to support their learning. An additional 12-15 hours per week are dedicated to schoolwork and job applications. Work-based learning helps to build an engineering identity (Johnson, Ulseth, and Raich 2022), and the BA intentionally builds that foundation.

All learning in the BA is digitally mediated meaning that there will be both asynchronous and synchronous portions of learning, with some students being on-site in Virginia, MN together and others who primarily be on Zoom in a hybrid fashion due to limitations on them being on-site. Technology has been integrated on campus to allow remote students to be a regular part of discussion and breakout groups within full-group, presentation, and classroom activities. This use of multiple media and tools for communication and construction ensures all students have access to learning opportunities – no matter their specific location or situation.

Student engineers also have several opportunities to practice communicating technical and non-technical topics to a variety of audiences using multiple media. For example, students present an IRE Talk, which is a TED-like talk on a topic of their choice, to faculty, staff, and peers to receive positive affirmations and areas for growth in their public speaking skills. They will continue to give IRE Talks in each subsequent semester to build upon their previous experience. Another example is the opportunity for students to present their design project. They do a presentation after each of the three segments of their project to faculty, staff, and other students in preparation for their final presentation to their client.

To facilitate and scaffold these activities, students are connected with a variety of faculty and staff members who help them develop their skills. Ph.D. professors facilitate technical learning while preparing student engineers to become life-long self-directed learners. Engineering professionals, which are referred to as program facilitators, from various engineering industries and other staff members facilitate most of the design and professional learning. These connections with professors and facilitators allow students to build fluencies with graduated levels of support for practice and performance. Learning can be more heavily scaffolded and supported by faculty and staff at the beginning of the BA, and these scaffolds can be gradually removed as students continue to grow and develop.

Each student engineer is assigned a program facilitator to serve as a learning coach to work one-on-one with. Conversations between the facilitator and student take place on a weekly basis in the BA to discuss the progress of short-term and long-term goals with relation to personal, technical, design, and professional realms. These meetings serve as a space for supporting planning and strategy development that is meaningful and relevant to the student’s learning.

Additionally, each student is assigned a learning journal reflection to write about an experience or area of development. The written reflections become an open dialogue between the learning coach and student engineer and a way to enhance student capacity for monitoring progress. Pluskwik et al. (2022) discuss the power of reflection and how it is practiced at IRE. They also highlight the benefits of the written documentation, which serves as evidence of student development, sparking conversation for continuous improvement within the program.

7 RESULTS & DISCUSSION

As described in the Methodology section, the results are reported in the form of a discussion of the approachable recommendations for implementation. The BA itself serves as a one-semester bridge program, but the components of UDL practiced in the academy to develop student engineers can be implemented in a variety of educational spaces including first year introductory programs, capstone experiences, and even in individual technical courses. There are pieces that can be implemented without an entire curriculum or program overhaul.

Reflection is one of the simplest implementations that can be integrated in a variety of ways. Allowing students space to reflect on their learning and growth will encourage their motivation and increase their ability to be responsible and self-aware student engineers. Reflections can be integrated as whole assignments, such as a learning journal, but can also be placed within other assignments, such as in student's notes, exit tickets, self-assessment, etc.

Career development is an effort that can and must be integrated within courses or programs at large. It cannot be expected that these developments will automatically happen. While some students may take advantage of a career center or workshops offered, in order to equitably prepare all students to thrive in their future workplaces, efforts must be intentionally included and required in classes and/or programs.

Existing capstone design projects in programs leave space for **just-in-time professional learning** in the realms of teamwork, conflict management, design strategies, etc. that can happen coupled with the project time. Many programs simply let students work it out, but there can be intentional learning and teaching efforts to help students improve their skills before entering industry.

8 LIMITATIONS & FUTURE WORK

This study was conducted by faculty and staff directly within or closely involved with the workings and purpose of BA. This perspective focused more on the design and implementation of the BA and its alignment with evidence-based teaching, which is much more logistical facing. As such, in the future, we would like to study student outcomes and perspectives of their BA experience when contrasted to traditional engineering programs. Employer perspectives also warrant a study to determine if the BA is succeeding in helping students be more prepared for industry placements.

9 CONCLUSION

Ultimately, the goal of the BA is to create a space where engineering students from all backgrounds are able to develop and practice the skills they need to become student engineers. The contrasting language between "engineering student" and "student engineer" illustrates the growth that occurs in the BA; rather than developing engineering students who are competent in textbook problems, the BA develops student engineers who are competent in technical, design, and professional skills. Integration of all aspects of learning is crucial to building the whole student. Engineering education cannot solely be focused on technical learning; real people need flexibility and support in the preparation to thrive in industry placements. The bridge-type style of the one-semester BA allows students to connect, adapt, and grow to an ever-changing world. This overall transformation allows them to thrive in their industry placements, which is evidenced by an industry partner who said, "IRE's new approach to education creates opportunities for talented individuals in a way that allows them to find and pursue their best. At IRE, they are not only creating value for their students, but they are also getting it right for industry. These are the types of initiatives that help shape our future."

ABSTRACT

Engineers of the future are being requested to become part of solutions for dealing with complexities in the world, exemplified by the adaptation of the 17 United Nations sustainable development goals (SDGs). Ensuring that engineering students are introduced to these is of the utmost importance, if sustainable solutions to grand challenges shall be developed, whether being of technological, social and cultural, and/or economic character. This paper entails a scoping review of the concept of mission-driven or mission-oriented innovation, as defined by the European Commission (EC) and the Organization for Economic Co-operation and Development (OECD), in engineering education research (EER). Seven papers were identified as relevant out of 50 papers derived from five databases, which were then reviewed by the two authors, indicating a substantial gap within engineering education research of mission-driven initiatives in education and research. It further reveals significant overlapping understandings, as the papers included often align their focuses with the SDGs without relating them to mission-driven or mission-oriented conceptual understandings. Outcomes of this scoping review propose that the field of EER acknowledges possible affordances, albeit challenges are still present, for engineering students in applying missions as a binding component for framing projects, cross-disciplinary collaboration, and partnerships with companies, authorities, or other stakeholders. Finally, future research directions are suggested in the field of EER with regards to mission-driven or mission-oriented innovation for grasping practical circumstances for staff and students involved in the works of dealing with complexities through missions.

1. INTRODUCTION

Since 2015, by the adoption of The United Nations Sustainable Development Goals (SDGs), member states of the UN have agreed to commit in seeking solutions for 17 overarching goals (The UN, 2016). This event has sparked shared support across international organizations and institutions as seen with The European Union (The EU) or The United States Government (The EU, 2023; NSB, 2020; Mazzucato et al., 2021). Foreseeing future impacts of global character for accommodating activities, strategies, or policies to solve the 17 SDGs is by default not achieved individually, as it requires multiple societal stakeholders to engage in collaboration to co-create innovate and sustainable solutions. A proposed framework concerning mission-driven and mission-oriented innovation policy (MOIP) has since emerged, which entails specific approaches for solving grand challenges related to the SDGs (Mazzucato, 2017; Purcell et al., 2019). Universities, nation states, the private and civil sectors are all requested to become involved across domains in solving specific missions and developing project-portfolios that can lead to innovative solutions for overcoming societal challenges (ibid).

Research and education are two pillars that shall contribute to positive changes, and herein are engineers a vital part (McQuarrie, 2022). Engineers have historically been involved in the transformation of societies dating back to the ancient civilizations of Greece and Egypt, and a great amount of the seven wonders of the world was designed by engineers (ICEE, 2021). Same needs can be transferred to settings of today, wherein engineering as an ability is required in the formation of solutions to the SDGs. In this matter, engineering education research (EER) plays a vital role in educating students that possesses skills and competencies to fulfil the UN's 2030 agenda (McQuarrie, 2022; Van den Beemt et al., 2020). However, since mission-oriented initiatives and grand societal challenges are complex entities, research and education cannot stand alone (Mazzucato, 2018; Wanzenböck et al., 2020). Both the civil society, policymakers, the private markets, and multiple governments have stakes in the sustainability agenda. In a political orientation, mission-driven and mission-oriented innovation is seen as pathways for decisions of economic nature (ibid.). Mazzucato and Wanzenböck et al. draws parallels to historical missions, such as the Manhattan project or the Apollo missions, that led to innovation in the stream of uncertainty and economical and technological advancements, producing both political and economic value (Ibid.). Today, even though no formal definition is developed by the OECD, there are found traces of what missions' entail: 1) directed, 2) challenge-oriented, and 3) boundary breaking (Wohlert et al., 2021). When perceiving mission-oriented innovation in settings of academia and higher education, the concept seems to consist of all the characteristics but seem to avoid politization when setting goals for mission-challenges. Research is a component in the processes occurring alongside the political sphere, although, abiding to strategies from both supranational and national levels (EUA, 2018). Arguments for the purpose of research and education institutions in this matter are found to be aligned with economic rationales, but perhaps as important is the transformative and innovative potentials of benefiting societies of the world (EC, 2019).

Engineers can be contributors to both factors, but questions arise concerning what engineering educations across the globe have initiated since 2015 in undertaking missions as core concepts of strategic relevance, and whether endeavours are found existing in literature pertaining to higher education institutions? Mission-oriented and mission-driven are terms that has undergone changes in understanding throughout recent times, as in systemic public policies (big science to meet big problems) or as in a contemporary setting to address grand societal challenges. The key differences can be said to relate to an element of time and endurance (Mazzucato, 2017). As of writing, there is not a large sum of universities worldwide that actively has sought to implement mission-orientation as their key argument in educational strategies. Whether it is due to political influences or intrinsic motivation is not the purpose of this study.

1.2 Purpose of the study and research question

Recent literature has echoed the gaps in the context of universities' adaptation of SDGs as core drivers for educational strategies potential partnerships for collaboration (Purcell et al., 2019; Chankseliani & McCowan, 2021). Suggestions are prescribed for establishing conceptualizations and frameworks to be applied, that can bring forth possibilities of facilitation of missions and mission-projects without constraining the dynamics of the respective institutions (Chankseliani & McCowan, 2021; HESI, 2021). The field of higher education has since 2015 seen a rise in research pertaining to SDGs, in some cases aligned with the concept 'third mission of universities' (Neary & Osborne, 2018), but it appears that the trend of mission-driven and mission-oriented innovation has yet to reach EER. If engineering students and researchers across the globe should play a vital role in these perspectives, additional emphasis should be advocated for in the field of EER, which this paper addresses with mission-driven and mission-oriented concepts as its point of focus.

This paper is a response to the scarlessly available research within EER related to mission-driven and mission-oriented strategies or experiments. Integration of formalized practices based on theoretical and conceptual understandings are being requested by the European Commission (EC, 2018), but as no strict decisions have emerged on how to incorporate missions as the steering drivers for engineering students or researchers, it presumably becomes detached from actual teaching, study, or research practices. Suggestions for initiatives can, although, be found in common European agendas of higher education relevance, as exemplified by the European University Association's 2026-agenda (EUA, 2023). Furthermore, as mission-driven and mission-oriented practices and proposals are created through political negations and strategic decisions, it is difficult to grasp circumstances for engineering students and researchers. To achieve a better understanding of what mission-driven- and mission-oriented strategies and related practices entail in engineering education, a scoping review is conducted to present current characteristics found in research revolving around these concepts.

The driving research question for this study is as follows: *What characterizes mission-driven innovation, mission-driven strategies, or mission-driven policies in engineering education research?*

2. METHODOLOGY

2.1 Protocol

As a guiding methodological framework, Arksey and O'Malley's framework for scoping reviews is applied since it is referred to as the acknowledged standard when undertaking scoping reviews (Levac et al., 2010; Pham et al., 2014; Tricco et al., 2016; Denton & Borrego, 2021). It consists of five stages: 1) Identifying the research question, 2) Identifying relevant studies, 3) Study selection, 4) Charting the data, and 5) Collating, summarizing, and reporting the results (Arksey & O'Malley, 2005).

The search queries for this study were completed in February 2023, in five databases: Scopus, EBSCOhost, Engineering Village, ProQuest and Web of Science. This was done for a thorough and holistic representation to be present, which emanated in several searches in multiple databases for documentation to increase the reliability of the findings (Denton & Borrego, 2021). The search did not include unpublished records, instead snowballing searches was done in Google (google.com and Google Scholar) to capture relevant studies not included or published in journals and conferences. An outcome was the discovery of review papers, strategic documents and funding information related to mission-driven or mission-oriented innovation (none of which had been through peer-review). Although, it did not bring forth relevance for engineering education, it was used to identify and cross-reference potential search words. The final search involved key search terms and to avoid limiting the potential results, it was intended to be broad in contrast to systematic literature reviews (Tricco et al., 2016).

(mission-driven OR mission AND driven OR mission-oriented OR mission AND oriented OR mission AND oriented) AND Engineer* AND Education* AND Sustain*

Figure 1 – Search terms applied

This scoping review does not entail a general overview of the state of MOIP as a concept, instead a solitary focus is placed on the terms mission-driven and mission-oriented innovation, which are used interchangeably for the purpose of this review, as the generic understanding applies to both terms (Wohlert et al., 2021).

2.2 Eligibly criteria

For this study, papers of all types were included in the initial screening of abstracts, however, to identify relevant studies limiters were applied based on following criteria: *year of publishing between 2015-2023, English Language*, *a Higher Education context*, *Engineering Education* or Similar wordings, *Sustainability* (or *SDGs*). The timeframe is set to entail publications after the adaptation of the SDGs by The European Union (2015), and the publications were required to involve *engineering education*.

2.3 Selection process

As scoping reviews can be defined as "a *type of research synthesis that aims to 'map the literature on a particular topic or research areas and provide the opportunity to identify key concepts; gaps in the research; and types and sources of evidence to* *inform practice"* (Pham et al., 2014), the readings of abstracts and full texts was mainly linked to the latter of informing practice and to demonstrate gaps in research. Considering the novelty of mission-driven and mission-oriented innovation in EER, the purpose is to understand the context and degree of prior research. The apparentness in how limited the research on the topic of mission-driven and mission-oriented is, can be exemplified by the relatively small number of results (N=74), which made the main reviewer omit the screening of titles, instead abstracts were read for the entire pool. The screening process was also characterized by inclusion and exclusion criteria being developed post hoc, as the increasing familiarity of literature provided leeway for determining relevance (Arksey & O'Malley, 2005). In the phase of screening full texts (N=13), four reviewers independently read the papers to filter out potential redundant articles, generate preliminary codes, and to determine the relevance for the research question. This was done in accordance with inclusion criteria from the main reviewer, which the review-team was presented before coding. A meeting was subsequently held by the review-team after the coding phase, to align findings and reiterate any opposing understandings, resulting in adjustments of codes and extracts for final included papers (N=7). It should be stressed, that for a certain degree of validity to exist, at least two or more reviewers should read, confer, and reiterate findings in any type of literature review. A summarized description can be seen in the flowchart below (Fig. 1).

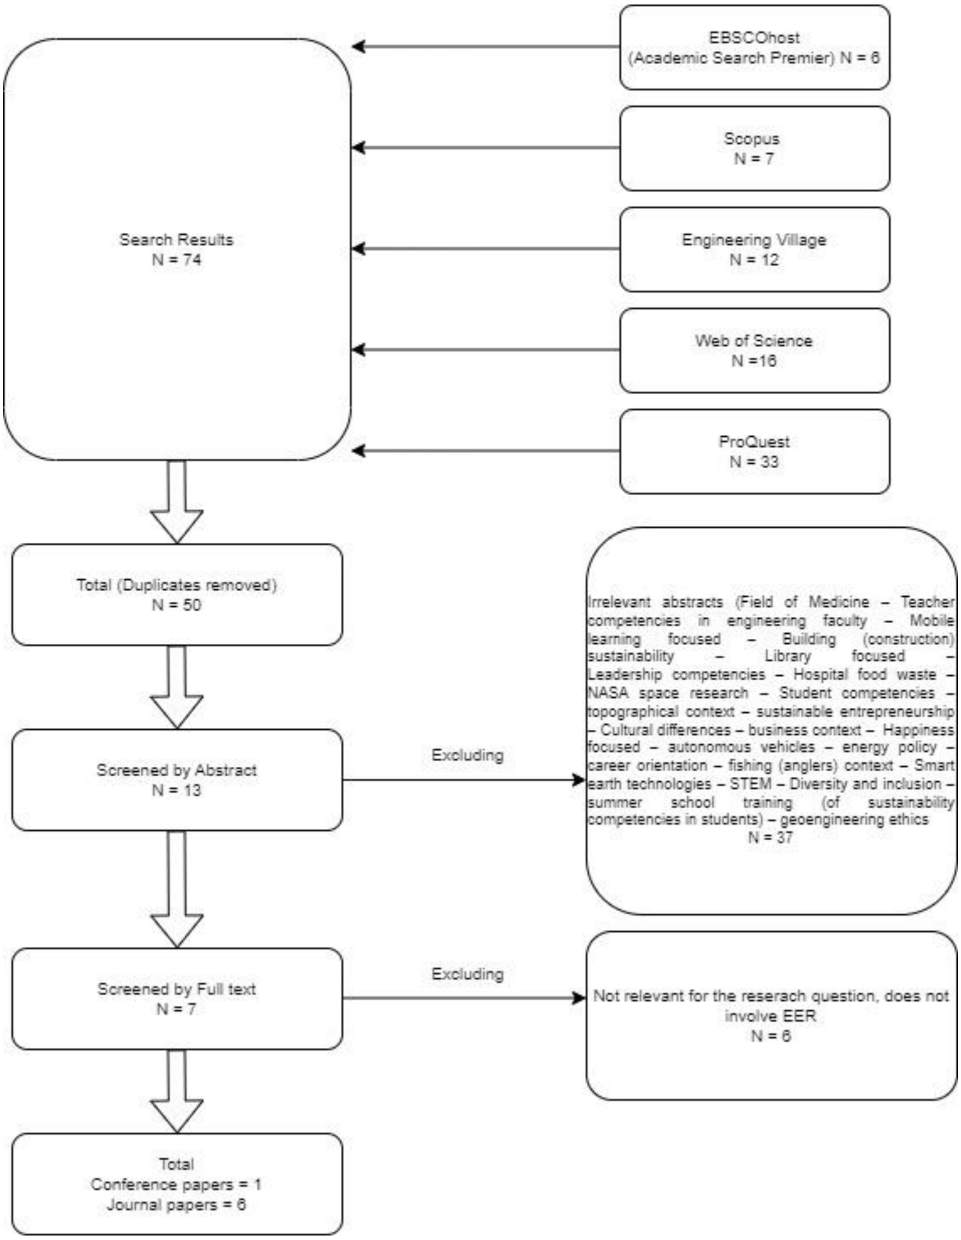

Figure 2 – Flowchart of the scoping process

3. Findings

Based on the charted data derived from extracts from the coding phase, the following section will present the outcomes found. A thematic inspired analysis, for summarizing information aligned with the research question, has been applied for the reporting of findings. These have, as Levac et al. (2010) suggest, a resemblance of similar qualitative analytical techniques which is not explicitly clear in Arksey & O'Malley's (2005) framework. The findings are organized based on three dominant categories: *Mission-driven and mission-oriented indicators*, *strategies and political processes*, and *innovation*. These have constituted the main theme of *characteristics in mission-*

oriented and mission-driven activities, processes, or projects in EER, which have led to three analytical themes: *Framing innovation, Strategic and political arguments*, and *Processes of mission-driven and mission-oriented innovation in EER*. It should be disclaimed that due the minimal appearances of mission-driven or mission-oriented framing or application at an institutional level in the seven articles, SDGs was also included during the coding phase, but without explicitly being used as a term for the search string. Again, this demonstrates the meagre focus on mission-driven and mission-oriented initiatives in EER, contrasting the commonly applied related framing aligned with SDGs (which are plentiful in research – as well in EER).

3.1 Summarization of papers

Table 1 present an overview of the articles included for this scoping review of mission-driven and mission-oriented innovation initiatives at engineering educations that exists in literature. However, as the final pool consist of a scarce and limited number of articles, this scoping review arguably functions as an indicator for the novelty of mission-driven proclamations in engineering education. The articles have been mapped according to year of publication, theoretical indicators, applied methods, whether they mention or relate to the SDGs or mission-driven and mission-oriented innovation, and whether empirical data is included, which they build their work upon.

In general, the generic information from the pool of articles resemblance the novelty of the concepts but also highlights that mission-driven and mission-oriented aspects and activities are few (almost non-existing) in engineering education. Combined with the notion of a minor use of empirical data, it showed that only 2 out of 7 articles build their arguments on empirical data.

Concerning the articles depicted use of methods, case-studies were most frequent (N=3) with interviews the second most frequent (N=2). It opens for question related to the general tendency that are common among all seven articles, which is whether the research objectives are placed on students, the organization, or research projects in a mission-driven and mission-oriented framing.

It appears to reflect the same tendencies as choices of methods when perceiving theoretical indicators, since theoretical arguments and explanations most often concern either a specific research project or student contexts. Enquiry-based or problem-based learning are found applied in 2 of the 7 articles but like categories of empirical data inclusion or method indicators, theoretical representations is also omitted in certain examples (N=2). System thinking and organizational theory both appear in one article each, arguably either concerning the institutional structures for mission-driven transformations into research or education or specific ways of framing sustainability at universities undertaking aspects mirroring mission-driven conceptualizations.

When perceiving how the articles depict their framing of core concepts as drivers for their research, both SDGs and mission-driven and mission-oriented terms are found applied. In mission-driven and mission-oriented innovation frameworks, such as

Mazzucato's (Mazzucato, 2017), it explicitly pertains to sustainable solutions – in a general sense according to the 17 SDGs. Articles included in this study either frame their context according to one of these or both. Most common in the content and purpose of the articles is SDGs as a main argument (N=5), indicating that authors acknowledge the importance of SDGs for constructing and steering their research. It is however, also commonly found that the concepts of mission-oriented or mission-driven innovation appear in similar frequency (N=4). What is quite interesting is how often articles present both terms consecutively (N=2). This indicates that the general framing accords to the 17 SDGs but simultaneously adheres to a specific understanding of dealing with the SDGs.

As no concrete requirements are placed upon the specific approaches for the processes of scaling grand challenges of society and the designs for dealing with missions (Mazzucato, 2017; 2018), it is, as described by Wanzenböck et al., likely due to the aspect of *growth* implicit in mission-driven innovation conceptualizations (EC, 2018). As missions are to be tackled in collaboration across sectors, divergent and convergent views on problems might be in risk of affecting the problem-solution space (Ibid.), and as described by the Global Research Council, missions shall be economically feasible, which can further hinder the aim for decentralized partnerships (UK Research & Innovation, 2019).

Table 1 – Overview of the papers included (with Paper IDs as points of reference)

3.2 Mission-driven characteristics in EER

The included articles for this study generally entail framings that peripherally mention mission-driven or mission-oriented innovation (or research and education) and SDGs to argue for the relevance of including the concepts in research or education in engineering educational contexts. Through the coding and thematic categorization, findings concern the characterization of mission-driven and mission-oriented concepts, as differences was found related to both on which levels and in which situations these concepts occur. It further seeks to encapsulate what the research question aims to uncover in explicating EER and examples of mission-driven and mission-oriented across published research. It should be noted that the novelty of mission-driven activities and processes in EER affected the thematic representation– therefore, an article is necessarily not applied in each analytical theme.

3.2.1 Framing innovation

In engineering education specific contexts, mission-oriented and mission-driven representations range from sporadic and minor involvement to explicit and concrete uses of mission-driven frameworks or conceptual understandings. In here, a strong buzzword appearing is *innovation*. In paper [a], innovation is applied as an urgent aspect for research projects working towards a stronger bridging of science and technology in a bio-economical perspective. They argue that support is needed to facilitate and sustain mission-oriented research by long-term commitment from industry and society and without it, innovation will cease to exist. Paper [f] frames innovation as a process that is bound to transform how institutions engages global issues that differs from previous technology-pushing solutions. The authors argue that pillar 2 in the Horizon Europe program is a direct framing of mission-oriented innovation policy for research institutions in the respective member states shall address system transformation in conjunction. Another framing of missions at an institutional level is found in the paper by [d], pointing towards a political dimension, as no grand challenge or mission-projects will suffice if not all relevant stakeholders, including governments and politicians, are collaborating internationally – both concerning research and decision-making.

3.2.2 Strategic and political arguments

The articles included do all, to various degrees, frame mission-driven and mission-oriented innovation in engineering education as being rooted in strategies and political processes. Differences are found to refer to either the purpose of research including both engineering and non-engineering disciplines, the financial support needed from governments or businesses, or trans- and international collaboration through initiatives from supranational institutions. Most frequent, when perceiving politics and strategies in EER concerning mission-driven and mission-oriented innovation, is the association made between funding, e.g., from the European Union, and the possibility to design and enact on missions and mission-projects (N=4). It can be, as [f] or [g] portrays, in the argumentation for choosing mission-driven research campaigns where politics and strategies appear, often related to specific supranational education and research initiatives such as Horizon Europe. Paper [d] describes, that the management of earth observation and geospatial big data require national partnerships with similar peers but also support from the Hungarian government and international alliances, although not involving missions but instead SDGs. The cross-case analysis produced by [c] explores how collaborative innovation was conceptualized by studying 15 mission-oriented ecosystems in Germany and found that the most important stakeholders to involve in mission-oriented innovation collaborations was politicians and political processes. If the presence of these were missing, financial support to the collaborative ecosystems would potentially cease to exist. Politics was also found to be directly linked to the prompting and scaling of solutions into society – both nationally and globally (Ibid.). An important aspect to consider, is the design of missions, the cross-sector collaborations that involve a mix of authorities, scientist, entrepreneurs, and the civil society, which can be complex and challenging to facilitate if decisions are made top-down [f]. Furthermore, if universities, and herein EER, shall become involved and heard in the process of creating innovation, external stakeholders, such as aforementioned, shall also proactively become engaged with educators that train students in mission-driven and mission-oriented approaches to education (ibid.). Transgressing borders of educational institutions and moving beyond internal structures of universities, is what [e] describes as a necessity for dealing with complexities (such as the SDGs) through research and education for generating long-term impact.

3.2.3 Processes of mission-driven and mission-oriented innovation in EER

As mission-oriented and mission-driven innovation in EER are relatively underexplored concepts, programs, courses, or research projects rarely involve concrete and explicit orientation towards existing frameworks. The pool of papers derived are primarily describing efforts and examples in ongoing and finished research, as the papers all are peer-reviewed and therefore work-in-progress and early stages of experimentation are perhaps yet to be submitted or published. The difference is whether research projects apply it into practice (N=3), or merely include mission-driven and mission-oriented concepts as argumentation for a relevance (N=4), often in conjunction with SDGs as a focal point. One example of a framing according to Mazzucato's mission-oriented innovation policy framework is found in the literature review of synergies between Enquiry- and Problem-based learning (EPBL) and mission-oriented innovation by [f]. They used their findings from the review to experiment in-situ with two undergraduate modules at the Faculty of Science and Engineering and Faculty of Business and Law (Manchester Metropolitan University). In these experiments, mission-oriented innovation and EPBL were constructed and applied in such a way, that both the university and surrounding industries and societal stakeholders was explicitly included in the attempt to establish cross-faculty interactions and inter- and transdisciplinary routines for both staff and students. Paper [c] examined the 15 technology-based ecosystems according to the concepts of mission-oriented innovation and grand challenges. This serves as an example on how ecosystems, wherein stakeholders from all sectors are collaboratively engaged, and both private and public entities support processes of innovation through funding. His proposal to successful eco-systems reflects a notion of bridging solutions across domains and interests, even when divergent perspectives exist. This implies translating grand challenges into missions that *value capture* rather than value creates, meaning even distribution of value among participants and stakeholders. The similarity between mission-oriented innovation and *system-thinking* is explored in paper [g], and their argument is based on the premise that system-thinking involves a holistic and multidisciplinary approach to problem-solving, where the focus is on identifying and addressing the root of problems, rather than just their symptoms. The necessity for interdependent and interconnected relationships between all included components and stakeholders is found in system-thinking, which can be transferred into a mission-oriented innovation understanding. To this, the authors argue, that SDGs and solutions to tackle them, are requiring cross- or interdisciplinary commitment, which makes a system-thinking approach suitable for creating coherent project-portfolios in relation to missions and promoting diverse research cultures (Ibid.).

4. Limitations, discussion, and recommendations

4.1 Limitations

To obtain a satisfactory degree of breadth and feasibility when identifying relevant studies, there have for the purpose of this review been excluded sources of information (e.g., grey literature or theoretical papers) due to the maintaining of comprehensiveness in the scope (Levac et al., 2010). It is acknowledged by the authors of this review, that potentially relevant studies have been in risk of being left out, but it is not an uncommon procedure for engineering education researchers occupied with scoping reviews to do so (Denton & Borrego, 2021). For retaining a concrete area of interest, further limitations arise by the exclusion of papers outside of Higher Education, in lieu, engineering education was selected to showcase the current gaps of mission-driven and mission-oriented research in that exact domain and to limit additional noise. The risk of neglecting valuable sources of information is therefore present, as this review did not seek to explore SDGs in higher education, but preliminary searches demonstrated that these are predominantly found in literature beyond EER and without being aligned with the terms of mission-driven or mission-oriented. In addition, a potential limitation concerning this study is the concepts of mission-oriented and mission-driven innovation in engineering education originated as a political idea and tool, and therefore examples that arise related to research or education across engineering education institutions rarely involve student activities, which also align with the final pool of articles and their expansion of focus to structural and educational political processes.

4.2 Implications for EER in mission-driven and mission-oriented contexts

The purpose of this scoping study was primarily to highlight the novelty and lack of research concerning mission-driven and mission-oriented innovation in EER – as commonly agreed upon in scoping reviews (Pham et al., 2014; Denton & Borrego, 2021). Reasons for why mission-oriented innovation concerning EER are limited, as of writing, is potentially related to the vast and incomprehensible number of stakeholders needed according to e.g., Mazzucato's mission-oriented innovation policy framework. Organizational theory can be used to argue for the intricate, and often complicated, nature of decision-making in organizations. Since mission-driven and mission-oriented innovation in Mazzucato's conceptual framework entails bottom-up processes, there can occur several difficulties related to a horizontal governance structure Bryson et al., 2006). Uneven balances and competing institutional routines and cultures can also prevent holistic and equal partnerships, and lack of commitment by stakeholders, which in return, demotivates and prevents the feeling of ownership (ibid.). Top-down decision-making in mission-oriented and mission-driven initiatives are also in risk of failure (Nutt, 1999). Often, managers or leaders tend to reward successes rather than failures (ibid.). This can potentially be argued for in business contexts that are market-driven, but in situations revolving around innovation through mission-projects, it is a guarantee that some will fail and not produce innovative solutions – but some will succeed (Mazzucato, 2018; EC, 2018). This is, although to a minor degree, also supported by findings of this review, as few examples were found to involve a clear and concrete involvement of mission-driven and mission-oriented concepts. For a deeper comprehension of the element of collaborating across disciplines, institutions, and sectors, a reference is made to Christiansen et al. (2023).

4.3 Recommendations for future research

Based on the findings, recommendations for further research should 1) consider entailing specific aims to uncover and design functioning ways of bottom-up mission innovation, 2) examine how cross-sectoral collaboration and mission-driven innovation in an engineering education context can establish research across sectors and domains with other disciplinary partners, and 3) re-conceptualize mission-driven and mission-oriented frameworks suitable for higher education, and preferably, include multiple voices and understandings in these designs, as the predominant framework currently used, developed by Mazzucato (Mazzucato, 2017; EC, 2018), is a solitary proposal – in some sense, contradicting the presented call for multiple and diverse perspectives.

ABSTRACT

As we move to a more sustainable world, expansion of education is key to the eradication of poverty (SDG1) and societal inequalities (SDG10). Global expansion of tertiary education offers opportunities to deliver Sustainable Development Goals by providing wide access to education in flexible learning environments. However, the quality of education (SDG4) must be maintained and enhanced as it is key to a partnership for the goals (SDG17). While increased learning online can facilitate achievement of these SDGs, there is also a move, within the education sector, to a constructivist approach and a more active learning environment. Interactive virtual learning environments (*e.g.* Virtual Reality) can offer considerable potential in the integration of active learning in an online environment

With this background in mind, the objective of this study was to evaluate the hardware and software resources currently available for effective delivery of remote virtual laboratory learning against nine technical, social and design criteria. At the same time, it is also important to consider sustainability in this evaluation including carbon (SDG13) and ecological footprints (SDG14/15). Hardware options examined were the Computer, Google Cardboard, Meta Quest 2 and Microsoft HoloLens 2, while the software platforms examined were H5P Virtual Tours, 3D Vista Pro, Dynamics 365 Guides and a professionally created VR platform. The main findings were that there is no 'one-size-fits-all' system and each system has its own advantages and disadvantages depending on the resources available at the institution and the type and level of knowledge and/or skill being delivered.

1 INTRODUCTION

1.1 Section 1

Virtual Reality (VR) technology has gained considerable traction in recent years, with applications spanning several industries, including engineering education. One of the most significant advantages of VR-based simulations is that engineering students can learn, practice, experiment, and make mistakes in a virtual environment, without the fear of causing real or physical damage. For example, in engineering, VR-based simulations can be used to train students on how to construct structures and how to test their designs in a formative way with minimal risk to the students. Furthermore, VR simulations can provide a realistic 3D environment, enabling engineering students to explore complex three-dimensional models from different angles and viewpoints, giving them a better understanding of the model's structure, function, and behaviour.

Another advantage of VR is that it can facilitate collaborative learning. This can be particularly beneficial in situations where students are located in different parts of the world from the teacher and where face-to-face interaction is difficult or not possible. This offers opportunities to deliver Sustainable Development Goals (SDGs) and the globalisation of teaching by providing wide access to education in flexible learning environments (SDG10). VR-based simulations can also be accessed remotely, making it easier for students to learn at their own pace, in their own time, and from any location. These simulations can increase student engagement and motivation (di

Lanzo et al. 2020) and can contribute to a higher quality education (SDG4). Additionally, students can learn at their own pace, with the ability to repeat simulations until they understand the concepts fully (di Lanzo et al. 2020; Al-Ansi et al. 2023; Soliman et al. 2021). More broadly, SDGs and sustainability concepts can be effectively incorporated into engineering education using virtual labs. For example, students can learn about renewable energy sources like solar, wind, hydro, and geothermal power in a virtual lab, which mimics real-world situations and difficulties pertaining to the creation, improvement, and management of sustainable energy systems. Finally, it should be noted that while VR does not replace the need for physically interactive labs, VR allows for increased student interaction, within the constraints of resources available (namely, lab time).

In summary, VR can be a significant tool for engineering education. VR-based simulations can provide students with hands-on training, enhance their visualization and spatial understanding skills, facilitate collaborative learning, and be cost-effective and flexible. VR can also increase student engagement and motivation, providing a more immersive and interactive learning experience. With the continued development of VR technology, its role in engineering education is likely to grow in the coming years.

2 METHODOLOGY

With this background in mind, the objective of this study was to evaluate the hardware and software resources currently available for effective delivery of remote virtual laboratory learning against nine assessment criteria, while also considering the impact of these technologies on sustainability. These criteria were identified based on the authors experience with the technology and are listed below:

1) Integration into Learning Management System (Moodle)
2) Integration of software and hardware tools (Cross-platform translation)
3) Immersive experience
4) Level of user interactivity
5) Ability of system to formatively assess and scaffold learning
6) Ease of use
7) Cost (user cost, institutional cost, maintenance cost)
8) Universal Design for Learning
9) Ethical issues (H&S, GDPR, etc).

Following the identification of the criteria, four different hardware platforms (Computer, Google Cardboard, Meta Quest 2 and Microsoft HoloLens 2), and four types of software (H5P Virtual Tours, 3D Vista Pro, MS Dynamics 365 Guides and a professionally created VR platform) were assessed for compatibility. Appropriate combinations (‘systems’) were then shortlisted for further assessment. It should be noted that the list of available VR/MR equipment and the software evaluated is not exhaustive, and this study represents a discrete examination of the potential options which were available to show the potential of VR as an engineering tool. A ‘least-required’ approach was also adopted, whereby if a software or hardware was considered useful on their own and worked across various platforms then they were included individually; on the other hand, if a hardware/software combination was required, then they were evaluated as such. The final systems that were identified for further evaluation were:

a) H5P Virtual Tours (H5P Group AS)
b) 3D Vista Pro (3DVista España S.L.)
c) Microsoft HoloLens with native apps
d) Microsoft HoloLens with Microsoft Dynamics 365 Guides
e) Custom-created VR platform (on Meta Quest 2)

Assessment factors such as ‘immersive experience’ depend on both the hardware and the software platforms and so they need to be assessed together. Therefore, 3D Vista Pro was assessed as a cross-platform system, as was H5P Virtual Tours, whereas, due to limited overlap, Microsoft HoloLens 2, was assessed separately with, and without, 365 Guides integration and the professionally produced platform will be assessed with Meta Quest 2 only, as it is the only hardware on which it runs.

Systems identified were evaluated in a semi-quantitative way by round table discussion of the authors. Dr Clarkin and Dr Obeidi used their first-hand experience of using these devices with student cohorts in conducting the assessment, while Dr Morrissey and Ms Ryan focused on the non-technical and social aspects of the evaluation. Each system (a-e) was assessed against each criterion (1-9) in a semi-quantitative scale from one to five, with one representing a low rating and five representing an excellent rating. A ‘heat map’ was subsequently produced and a percentage score calculated (Table 1).

No student assessment was carried out in this study as this represented a ‘first-step’ in the system evaluation. It is envisaged that a student-centred study will be carried out in the near future to further evaluate the systems.

3 RESULTS

The findings from the initial analysis of different hardware and software combinations are shown in Figure 1. Following a technical analysis based on the nine criteria, a summary table of the findings is shown in Table 1.

Figure 1: Venn Diagram outlining interaction between different hardware and software options, associated costs and traffic light overall ratings.

Table 1: Summary evaluation of the VR systems from 5 (excellent) to 1 (poor)

Assessment Criteria:	H5P Virtual Tours	3D Vista Pro	HoloLens with native apps	HoloLens with MS Dynamics	Custom-created VR platform
Integration into Learning Management System[a]	5	4	1	1	1
Integration of software and hardware tools[b]	3	5	2	2	2
Immersive experience[c]	1	2	3	5	4
Level of user interactivity[d]	1	2	3	5	4
Ability to scaffold learning[e]	3	4	2	4	3
Ease of use[f]	5	4	2	1	1
System Cost[g]	5	4	2	1	1
Universal Design for Learning[h]	3	4	2	3	3
Ethical issues (H&S, GDPR, etc)[i]	5	4	3	3	2
Total Points (out of 45):	**31**	**33**	**20**	**25**	**21**
Percentage (%):	**69%**	**73%**	**44%**	**56%**	**47%**

Integration into our Learning Management System (LMS) (a). HP5 Virtual Tour is already integrated into DCU's learning platform 'Loop', a Moodle platform, and data from quizzing can automatically move into the Moodle gradebook. 3D Vista Pro can be exported as a SCORM package, which can then be uploaded to Moodle. This is useful when quizzing elements are incorporated into the 3D Vista Pro experience. However, many LMS systems have upload limits set by the administrator and where data intensive elements such as 360 videos are incorporated into the 3D Vista Pro experience this may cause issues. Additionally, grading elements do not transfer across systems, so if using the 3D Vista Pro experience on the Meta Quest 2 this will be independent of the LMS and quizzing elements will not automatically transfer. None of the other systems allow for integration in the LMS.

Cross Platform translation (b). As indicated in Figure 1, 3D Vista Pro integrates across several different platforms while H5P Virtual Tours had some, but minimal, cross-platform integration. The other systems were linked to their individual devices but integrated well overall with those device/software combinations.

Immersive experience (c) and Level of User interactivity (d). Both the custom created VR platform and the HoloLens with Microsoft Dynamics 365 Guides performed well under this criterion. Though it is difficult to compare MR with VR, while both are truly immersive, the HoloLens with Microsoft Dynamics 365 Guides, because of the integration with the real environment and movement, is rated slightly higher.

Ability of system to formatively assess and scaffold learning (e). For hands on learning HoloLens with Microsoft Dynamics 365 Guides far outpaces any alternatives but for information-based learning 3D Vista Pro is very useful for more traditional quizzing options. H5P Virtual Tours does provide quizzing options but those options are very limited. Surprisingly, though one can embed 2D video content (e.g. from YouTube) into H5P Virtual Tours, it does not at present allow for integration of 'H5P interactive video' content with embedded quizzing, which would be a considerable advantage to the system.

Ease of use (f) was evaluated predominantly from the instructor's perspective, but where systems are intuitive for the students they will also ease the burden on the instructors and the resources required to run VR/MR sessions. The H5P Virtual Tours are very intuitive for learners and will require next to no instructor intervention. 3D Vista Pro is similar in this regard, with very minimal instructor input requirement, even when students are first time VR/MR users, which is generally assumed. The other modalities will require some time for users new to VR/MR to become familiar, though it is expected that this will reduce with societal adaption of VR/MR technologies in general. As a result, the amount of instructor resources required for these sessions can be considerable and the time required for allocation of these sessions will be longer.

***System costs* (g)** were evaluated with regard to user (student) costs, institutional costs and maintenance costs. H5P Virtual Tours is free on Moodle and so it was rated highly. 3D Vista Pro has a nominal cost for content developer (€499+vat) and no costs for users. However, this assumes that the system is to run on a PC, for which the cost is not included. However, in the future, and in certain developing economies where PCs are less commonplace this may be worth considering in more detail. It should also be noted that '3D Vista Pro hosting' adds considerable ease of use for the instructor, avoiding multiple uploads to multiple devices and making integration with Google Cardboard much easier, but at a cost depending on the amount of data space required.

Both Microsoft HoloLens and associated 365 Guides represent a considerable cost to facilities, costing ~€4,000 per unit of hardware and anywhere between €708-€1,956 per year (Microsoft 2023). Custom developed VR content can be very expensive when outsourced to professional companies (~€15,000-€30,000). However, the reuse of such systems over the years for many students can reduce the cost to a per student basis but headsets (in this case Meta Quest 2) are still required to be purchased on top of this cost, adding ~€499 per headset.

Universal Design for Learning (UDL) (h). All platforms score low in terms of '*choice of assessment instruments'* but 3D Vista Pro, H5P Virtual Tours and HoloLens with Dynamics 365 Guides do provide for assessment instruments, which can be seen as an alternative assessment means. All platforms score low in terms of providing '*different types of media*' but 3D Vista Pro slightly higher due to its ability to be used on multiple devices. HoloLens with 365 Guides is the only platform that can provide a limited opportunity for collaboration. As the platforms and systems develop, the authors are of the opinion that multi-user experiences will become more commonplace, which would be advantageous in terms of adopting UDL principles.

Ethical issues (i) were evaluated with regard to health and safety concerns and GDPR/user data issues. Neither H5P Virtual Tours nor 3D Vista Pro gather personal data or require login in and of themselves. However, Meta Quest 2 used with 3D Vista Pro or the custom VR Platform does require Facebook sign in. HoloLens with Dynamics 365 Guides is designed around data and gathering of employee data for company analysis (*e.g.* optimisation of production lines). For HoloLens and associated software, Microsoft does gather some data and your organisation will also potentially gather data. It is difficult to fully ascertain the level of data risk with Meta Quest 2 but certainly there is lots of concern. The scope of this project did not allow for a full analysis of the management of data across the different systems and associated use or risk of data leaks but this is certainly something that should be considered in by individual institutions in adopting these technologies.

Though this analysis compared and evaluated different VR/MR systems against one another, there is no 'one size fits all' system and each system has its own advantages and disadvantages depending on the resources available at the institution and the type and level of knowledge and/or skill being delivered. To further assist with this evaluation, the VR/MR systems were also evaluated in terms of Bloom's taxonomy (Figure 2). The 3D Vista Pro and H5P Virtual Tours systems were found to be very flexible and adaptive, easy to use systems but they have limited interactivity and so are best suited to delivering knowledge (Blooms Level 1). The custom developed VR platform in combination with the Meta Quest 2 provides considerably more comprehension capabilities (Blooms Level 2), delivering a more interactive experience but with limited formative assessment capabilities. The HoloLens with Dynamics 365 Guides offers a truly immersive experience that scaffolds user learning in an experiential way and allows them to apply their knowledge (Blooms Level 3) and analyse options (Blooms Level 4); however, the costs can be prohibitive, and use is restricted to a single platform. An ideal scenario would be to provide a multiple systems approach to student training, whereby a simplified introduction to the 360-degree space, with embedded knowledge acquisition is provided by a platform such as 3D Vista Pro. Once complete, students could learn the more interactive requirements of the system using a custom developed VR platform on the Meta Quest 2. Once students are familiar with the requirements to operate the system they can move on to a guided operation with the machine (or machine analogue) using the HoloLens with Dynamics 365 Guides. This will provide a fully automated training system through use of VR/MR platforms. This will provide students with more access to the higher levels of Bloom's Taxonomy (evaluation and synthesis) and future iterations of the systems may allow students to design and test hypotheses and experiments in the virtual world by providing limited branching scenario within the VR/MR platforms, allowing them to better apply and analyse both real world (thorough MR) and virtual (through VR) data.

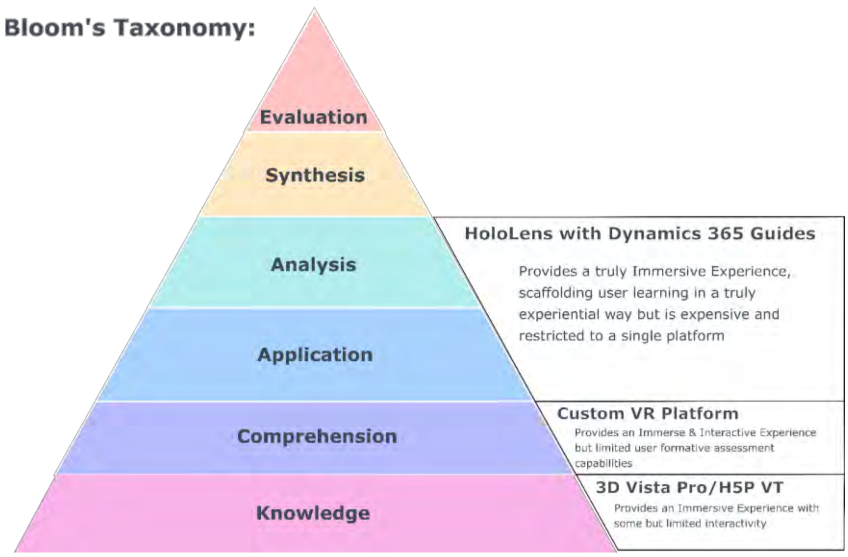

Figure 2: Bloom's Taxonomy Analysis of Three VR/MR Systems

4 SUSTAINABILITY CONSIDERATIONS

Sustainability is a key factor in all industries including engineering virtual reality labs and additive manufacturing as a good example. Below, a summary of some strategies for incorporating sustainability into these fields (Peng et al. 2018; Sandhu et al. 2022, 4-9; Ball et al. 2019, 3-25).

i. **Energy efficiency**: Making sure the used equipment is energy-efficient is a significant approach to encourage sustainability in VR labs. This can be done by adopting energy-saving features like automated shut-off or power-saving modes or by selecting equipment with high energy efficiency ratings (Vo and Huesmann-Odom 2023, 4-9).

ii. **Use of renewable energy sources**: Using renewable energy sources to run the VR lab is another approach to enhance sustainability. In order to lower carbon emissions and energy costs, one option is to produce power using solar or wind energy.

iii. **Recycling and waste reduction**: Unused materials and unsuccessful prints frequently result in a large quantity of waste in additive manufacturing. Utilising recycled materials, improving designs to use less material, and implementing a recycling program for unused materials and unsuccessful prints are all ways to reduce waste and promote sustainability.

iv. **Sustainable material selection**: By choosing sustainable and ecologically friendly materials, additive manufacturing may also be made more sustainable. For instance, using biodegradable materials, it is possible to make items that are both easily biodegradable and environmentally friendly (Reen et al. 2021).

5 CONCLUSION

In conclusion, the integration of virtual reality in engineering education holds immense potential for revolutionising the learning experience. By providing immersive and interactive simulations, fostering spatial understanding, and promoting active learning, VR can enhance students' engagement, comprehension, and practical skills. Addressing the challenges of affordability, technical expertise, and accessibility in line with the SDGs, will be vital in realizing the full benefits of VR technology. With continued research, development, and collaborative efforts between educators, engineers, and VR experts, the future of engineering education stands to benefit greatly from the integration of virtual reality. Each VR/MR System has its own advantages and disadvantages, and educators should choose the combination of hardware and software that best meets the learner needs and learning outcomes required. Providing cross-platform options is also highly recommended where possible, to provide the learner diversity of interactions and cater for diversity of learners.

Keywords: *Engineering Skills: Competency Growth: Further Education: Cohesiveness in Education*

ABSTRACT

In both the UK and EU there is a growing awareness of the need for Higher and Further Education (HEIs / FEIs) institutions to work together to provide high quality engineering courses able to meet the needs of an increasingly technical and knowledge-based economy (Barrichello et al., 2020, Giraldo, 2022). This paper focuses on learning and teaching in one particular engineering area, that of '*electrification'*, it reflects upon moves to create a regional multi-level educational strategy built upon the development of expertise at partner FEIs.

As one of the UK's leading Engineering Education providers at tertiary level, WMG is leading this boundary-crossing project. An Action Research approach has been developed that transcends organisational competitiveness by creating a multi-level approach to the provision of electrification skills amongst the population of the West Midlands.

[1] Author for Correspondence: benjamin.silverstone@warwick.ac.uk

Four different project objectives have been developed:

1. Analyse stakeholder need from the perspective of employers, students and colleges.
2. Analyse extant provision per FEI in terms of physical and human resources
3. Identify any gaps in provision of training available within the region.
4. Develop a plan for the establishment of Centres of Excellence across the region.

This paper discusses the need for synergising provision within what is very much a Quasi Market (Donovan, 2019). It suggests that rather than compete with each other, FEIs need to be working together, and in partnership with HE, create high quality, industry driven and cohesive regional provision. In an emerging field such as ‘electrification’ (of transport and in terms of new battery technologies), the need for regional focus and expert leadership has become increasingly important.

1. INTRODUCTION & BACKGROUND

Following Brexit, longstanding concerns regarding skills shortages in engineering in both the UK and EU has resulted in a growing need for the University, Vocational and Further Educations sectors to work together to provide high quality engineering courses able to meet the needs of an increasingly technical and knowledge-based economy (Barrichello et al., 2020, Giraldo, 2022). This concept paper, which is written at the very early stages of the project, begins by looking at moves by the UK government to begin to address UK engineering skills shortages. It continues by describing how one University, in collaboration with local Further Education providers (Vocational Education & Training), is planning to assure that the F.E. Sector in the West Midlands Region has the capacity to provide sufficient numbers of skilled engineers equipped to work in the ‘electrification’ sector.

One of the keyways in which skills shortages are being addressed within the UK, both in the engineering sector, but also much wider, is through a recent *reinvigoration* of traditional style apprenticeships. Funded through a range of industrial taxes, level three and level four apprenticeships are offered by F.E. colleges, often in partnership with universities. Generally aimed at those over 16 years, apprenticeships provide a direct route into either employment or university. Students study for a level three and or a level four qualification spending most of their time in work.

In the UK. the term apprenticeship represents a formal period of training which lasts between 1 and 5 years, depending on the level of study. There are four levels of apprenticeship, each equivalent to a recognised UK education level; these are:

- Intermediate Apprenticeships (Level 2: Equivalent to GCSE [General Certificate of School Education]).
- Advanced Apprenticeships (Level 3: Equivalent to GCE ‘A’ levels [General Certificate of Education, Advanced]).

- Higher Apprenticeships (Levels 4, 5, 6, and 7: Equivalent to Foundation Degree and above).
- Degree Apprenticeships (Levels 6 and 7: Bachelor's or Master's Degree). **(Gov.UK, 2023)**

Table 1 shows the numbers of students enrolled in STEM apprenticeship programmes over a four-year period (as well as depicting those enrolled in a business, admin and law apprenticeship). It should be noted that it is not possible to access more focused data on gender, ethnicity or previous education of students.

Table 1: Apprentices Enrolled in Engineering & Associated Subjects – 2018/19-2021/22 (Gov.UK.2023a)

Year	**2018/19**		**2019/20**		**2020/21**		**2021/22**	
Subject	*N*	*%**	*N*	*%*	*N*	*%*	*N*	*%*
Business, Administration & Law	118,600	30.2	94,400	29.3	95,900	29.8	93,900	26.9
Construction, Planning & Built Environment	22,500	5.7	21,900	6.8	20,000	6.2	26,100	7.5
Engineering and Manufacturing Technologies	60,000	15.2	52,000	16.1	39,500	12.3	49,100	14
ICT	21,100	5.4	18,200	5.7	18,400	5.7	22,800	6.5
Science & Maths	100	-	200	-	200	-	400	-

** The % Table depicts the percentage of apprentices enrolled in the subject as against the sum of all those enrolled on apprenticeship programmes (when n = 100)*

When considering the need for Further Education to provide skills training for the Engineering Sector, Table 1 reveals a concerning picture, showing that there are twice as many business apprentices as there are those enrolled on engineering and manufacturing courses (Gov.UK, 2023). Furthermore, in the ICT and Construction Sectors the situation is even more dire, with only 6.5% and 7.5% respectively of all student apprentices working and studying in these areas.

Whilst apprenticeships are perceived to be aimed at young people, other training has recently become available for adults. A new government "Skills for Jobs" initiative launched April (2021) aimed to provide adult learners, aged 19 and over, with the opportunity to study for a level 3 qualification in a subject that would equip them with the skills employers' are seeking, thereby enhancing individual job prospects (Dept. of Education, 2021). This initiative provides free training in a number of different areas where there are national skills shortages. It targets those in receipt of unemployment benefit and promises a level 3 qualification and route into employment.

Unfortunately, as detailed in Table 2 below, the success of this initiative is somewhat debatable, although those training in construction, planning and the built environment are twice as likely to succeed than those training within the business area. Interestingly, a cross tabulation of the data revealed a ‘gender attainment gap’ in four of the five areas examined; with male students between 5-16% more likely to succeed and pass the course than female students.

Table 2: Adult Education: Skills for Jobs (Students Aged 19+ Studying Level 3 Engineering & Related Topics at Further Education: 2021 / 2022) (Gov.UK.2023b)

Subject	Enrolments			Successful completions & graduation			Percentage of students succeeding**			M/ F Attainment Gap***
	All	F	M	All	F	M	All	F	M	
Business, Administration & Law	6290	4610	1680	1410	980	430	22%	21%	26%	5%
Construction, Planning & Built Environment	4430	170	4260	1810	50	1760	41%	29%	41%	12%
Engineering and Manufacturing Technologies	2060	170	1890	690	40	659	33%	24%	35%	11%
ICT	2480	910	1570	900	290	610	36%	23%	39%	16%
Science and Maths	230	150	80	30	20	10	13%	13%	13%	0

***The percentage of students succeeding is shown within the subject area.*
****The M/F attainment gap refers to the percentage difference between genders of those who succeed and complete the course.*

Having briefly examined the background of training in the F.E. Sector in the UK, the following paragraphs provide a brief insight into a regional initiative aimed at addressing skills shortages in the engineering electrification sector. It is important to note that the project is very much in it’s infancy. It is acknowledged that there is much work to be done including a wider literature review of the extant literature pertaining to collaborative working between H.E. and F.E.

2. ELECTRIFICATION IN THE WEST MIDLANDS: PROJECT OBJECTIVES

The overarching objective of the project is to prepare the West Midlands Region to react effectively to the changing market demands that electrification is presenting as society moves towards more sustainable technology. The project aims to promote collaborative working between H.E. and F.E. Institutions within the West Midlands. It will ensure that learners are able to access education and training opportunities that will lead to employment, whilst also ensuring that the West Midlands region remains an attractive prospect for inwards investment.

One of the key drivers for the project is the West Midlands Combined Authority (WMCA) which has identified transport and energy as key strategic sectors for the region. This is reflected in the Local Skills Improvement plan. Much of the responsibility for providing education and training will fall on the Further Education sector with c80-

85% of roles requiring training to levels that FE specialise in (this Table is based on the proportion of electrification roles employed with levels of education congruent with FE College delivery. Ensuring that Colleges are prepared to respond to this demand through sufficient capital and operational funding will be critical to the future success of the region.

The project will also drive F.E. Colleges to collaborate more closely with each other together than previously. Whilst numerous previous capital projects have required a level of such collaboration across the F.E. Sector, colleges are necessarily isolationist in a lot of their provision (something which is necessary to maintain competitive advantage within the QUASI market that is the UK F.E. Sector). Taking a regional view exposes the types of skills provision where duplication can readily be supported as the market is big enough.

Colleges West Midlands suggest that at lower levels, college learners are less likely to travel beyond their immediate locality, whilst for more specialist, and higher-level courses, learners are more prepared to travel at further. To avoid future duplication of provision, a wider view needs to be taken to ensure that specialist provision can be accessed with the region. Collaboration across the F.E. Sector will involve the sharing of human and physical resources as well as intellectual property. There is also a need for an institution to take a leadership role, which is where WMG, University of Warwick will step in.

2.1 The 'Market'

Most providers in the region are focused on providing skills for EV servicing. This is in response to the most visible, and clearly defined, need within the current market. However, a wider strategic view of the demands that electrification will bring demonstrates that a focus on the underpinning technologies associated with electrification is also needed. This will enable providers to react more effectively to industrial needs and in doing so expand provision beyond the EV market.

Developing specialisms in batteries, motors, power electronics, robotics and software and hardware engineering, amongst other technologies, will help to secure the region's emerging skills requirements.

3. DISCUSSION: THE CHALLENGES OF COLLABORATIVE WORKING IN WEST MIDLANDS FURTHER EDUCATION SECTOR.

The first phase of the project requires that the WMCA be presented with capital and operational strategic plans to be implemented from the 2023/24 year. The regional approach to capital requests covers a range of different areas such as funding for public engagement and staff. It also identifies four challenges of collaborative working that the project seeks to address. Each of these is now discussed.

3.1 Stakeholder Analysis: What do employers, students, colleges and WMCA want the F.E. Sector to Provide?

Due to their close links with the communities serve, F.E. Colleges are best placed to understand, interpret and react to stakeholder needs. Provision within the F.E. Sector tends to be demand driven and requires a proven market need before courses are made available. However, work undertaken as part of the National Electrification Skills Framework has shown that many employers are not clear about what is required and therefore any skills- needs analysis should look both at the potential for stimulating the market as well as the ability to react to it.

Whilst there is some interest being shown by students themselves in electrification, most young people are unaware of the employment opportunities a career in engineering is likely to offer. To address this there is a need to raise awareness of engineering much earlier in the education journey. One of the key aims of this project will be to establish the means to engage with the Schools Sector, raising awareness of engineering in general and the opportunities training in 'electrification' may bring in particular.

Colleges themselves are key stakeholders in this process and it will be critical to understand the level of engagement they wish to have with a regional strategy. With each college acting as an independent business there are pressures to ensure that they remain individually viable whilst also exploring collaboration. There is precedent for collaboration as seen in requirements for funding which stipulate that bids need to be carried out as part of consortia to limit the dilution of funding. However, where there is duplication of provision there will be natural competition between colleges. This project will take account of this nuanced relationship and identify where duplication of provision, and hence competition, is beneficial to the overall skills landscape. In such cases the project will highlight where collaboration could prove to be the most effective way of ensuring that the region has the educational support and backing it requires.

Finally, the combined authority itself is also a key stakeholder in this initiative. The overall competitiveness, and therefore success in attracting and retaining investment, is critical to the growth of the region. A strong F.E. sector that can provide the skills environment to attract, and retain, employers engaged in electrification will be critical. This stakeholder interest will be realised in the investment provided as a result of the initial report outcomes.

3.2 Identify Extant Provision Per F.E.I. in terms of Physical and Human Resources

There are three key components to this objective, the analysis of current and future planned capital expenditure, the current curriculum, and current human resources. Understanding these in the context of one another, allows for the establishment of current capability and capacity across the region so that planned growth and the ability to deliver against ambition can be realised.

There are a range of physical resources across the region relating to electrification, most of which currently focus on EV servicing and repair. There are also other assets, allowing for delivery of courses to drive capability in other transcendent (e.g., digital) technologies, which are not as immediately apparent. Understanding the extent of physical resource will speak to the current capacity to deliver against electrification competencies. An analysis of current provision will also enable a map of resources to be created to show gaps in coverage that need to be addressed. It is also important to understand planned expansion of facilities as this will inform the potential to grow provision as well as demonstrate capacity growth to WMCA.

Linked to physical resources, is the curriculum. Understanding the scope of provision across the region, as well as planned growth, will enable gaps in academic and skills training provision to be mapped out, and opportunities to be identified for new courses to be developed. Such an analysis will also highlight where employer needs are being met. From the WMCA perspective, understanding the potential capability that will be delivered in the future will allow for speculation around inward investment.

Finally, human resources represent the most critical part of this objective. One of the core driving factors that has influenced the overall strategy is that it has proved to be challenging to ensure that F.E. colleges have the appropriate capability to deliver the required courses. Another challenge represents FEIs' ability to attract, recruit and retain future engineering talent. Without this there is little point in investing in facilities or planning new curriculum. Understanding the status of human resource will enable development plans to be implemented to ensure staff receive appropriate training in line with curriculum growth and that other methods of ensuring that there is sufficient coverage, such as industry secondment, can be explored in conjunction with WMCA.

3.3 Identify Gaps in Training Provision across the Region.

The first two objectives will help to identify current gaps in the provision on offer and enable strategic investment to be made to ensure that facilities, human resources and accredited and approved engineering curricular are in place to meet need. Closing the gap in training provision will also highlight opportunities to attract new investment into the region where the skills environment is present.

The identification of gaps also links closely to analysing where provision can be duplicated and where specialist provision needs to be located. It is suspected that some gaps in provision will be as a result of individual colleges being unable to make a successful business case for the provision of a particular course based on low demand. In these cases, gaps may be closed through collaboration where low numbers can be combined. In addition, there is a case to look at specialisations where colleges who are focused on key technologies will be able to create focal points and close gaps through engagement and collaboration.

Critically, the speed of the way that the electrification landscape is changing means that there will always be gaps opening and closing. The ability of colleges, through their physical and human resources, to adjust and evolve the curriculum will be key in meeting this challenge. When considering capital, and operational, investment there will be a need to engage with organisations, such as the UK Foresighting Hub, to continually look to the future of capability need.

3.4 Develop a Plan for the Establishment of Centres of Excellence Across the Region

When focusing on electrification the decision has been made not to focus on traditional sectors but to focus on enabling technologies. These are termed as transcendent technologies due to their role in transcending the sectors in which they are applied. Whilst sector applications will drive much of the curriculum in the region, e.g., servicing of EV which encompasses a number of the transcendent technologies applied in an automotive context, there is value in having centres that provide focal points in the specific technologies themselves.

In putting the strategy together, the need to establish centres of excellence across the region has become evident. Individual colleges specialising in different skills provision and training need to work together to establish a network of provision purposefully focused on addressing the needs of regional industry. Having such focal points will provide two key advantages. Firstly, where there are gaps in curriculum caused by low student numbers across different providers, centres of excellence can enable viable provision to take place. As such they can address niche requirements across the region in a strategic way bringing students together to study in a particular area. Such centres of excellence will also provide regional leadership in their respective technologies, supporting other providers in areas of best practice.

The 'Centres of Excellence Model' is untested in Further Education and will require further analysis to establish its viability, but there are already examples of providers across the region that could take on this role for specific technology domains. The main challenge likely to be faced in developing the strategy is the willingness of individual F.E.I.s to engage in a collaborative manner to ensure regional success. The idea of Centres of Excellent is, at this moment in time, aspirational but it is envisaged that as the project moves forward the synergetic value that specialisation and collaboration can bring to the region will become a reality.

4. CONCLUDING REMARKS

This brief conceptual paper has set out four challenges faced by West Midlands F.E. Education Sector in developing a strategy for collaborative working so as to meet the future needs in the area of 'electrification'. The role of the WMG, University of Warwick, in this strategy is one of facilitation and leadership, bringing the partners together, writing the WMCA funding bid and acting as a central hub where organisational difficulties and challenges may begin to be addressed.

In conclusion, this project is very much in its early stages. Discussions between the University and local F.E. colleges have promoted a positive response, boding well for the future. Yet much of the detail remains undecided. The presentation accompanying this paper will report on progress, outlining future plans for collaborative working and identifying the challenges faced and overcome. It is anticipated that, by the time of the conference, the regional strategy discussed here will have become a reality. Plans for 'Regional F.E. Centres of Excellence' will hopefully be well underway and many more opportunities will be opening up for next year's cohort of future engineers. Watch this space. The future promises to be exciting!

The use of Peer Assessment and Group Peer moderation to develop 'soft' skills in Engineering students researching Sustainable Energy

R. Cole [1]
School of Engineering, University of Limerick
Limerick, Ireland
ORCID 0000-0001-7739-5117

Conference Key Areas: *Embedding Sustainability and Ethics in the Curriculum; Engineering Skills and Competences, Lifelong Learning for a more sustainable world*
Keywords: *Peer assessment, peer moderation, communications skills, sustainable energy*

ABSTRACT

Since the change to an outcomes-based approach in Engineers Ireland's accreditation criteria almost 20 years ago there has been an emphasis placed on 'soft' skills such as teamwork and ensuring graduate engineers are not only well versed in their chosen discipline, but that they can communicate their knowledge – to other Engineers and also non-Engineers. Energy Management is a module taught to 4th year Mechanical Engineers, and the learning outcomes are best assessed by how students can communicate the energy topics they are researching. As an individual they will research an area that interests them and write a paper at the end of semester but leading up to this there are two 'patchwork' assessments from which they receive feedback and can use to formulate the introduction to their final paper. The second of these is peer assessed using the same Rubric as for the first assessment, and they must also review their own writing following this. Feedback has shown that this develops a greater understanding of their writing and what constitutes a good technical writing style. Teamwork is developed in this module through a 35% sustainable energy group project which involves a presentation and a written group report. On completion the students submit a peer moderation form online which allows the grade to be moderated if the work was not evenly shared. The approach taken for each element has evolved over 15 years and will be explored as part of this practice paper.

1 INTRODUCTION

The importance of communications skills and teamwork for Engineering graduates was emphasised with the introduction of outcomes-based criteria for Accreditation of Engineering programmes in Ireland in 2004, prior to this the criteria to accredit programmes was input-based. Successive updates to the criteria continue to stress the importance of these 'softer skills', with the latest version also introducing outcome criteria around Engineering Management and Sustainability (Engineers Ireland, 2021). It is simply not enough for an engineer to be technically competent; they need to be able to communicate their engineering solutions to other engineers, and also to non-engineers. In 2007 I took over the delivery of a 4th year Mechanical Engineering module – Energy Management. The syllabus covers global and national energy usage and policies, energy and the environment, an introduction to renewable energy, and Combined Heat and Power (CHP). It also covers the thermodynamics behind increasing the efficiency of fossil fuel-based energy production. In the first year, I assessed it as had been done previously, 70% terminal exam and 30% coursework, however it was clear to me that there was a very shallow learning involved in the energy topics, with students typically answering the exam questions with short, bullet like responses. At this time, I was also undertaking an MA in Academic Practice, where I first engaged properly with pedagogy. Biggs (2003) constructive alignment resonated with me, helping me to construct learning by aligning my teaching and developing more active learning to move students away from the tendency to rote learn for terminal exams.

To encourage deeper learning and develop critical understanding and writing skills I endeavoured to change part of the assessment to Patchwork Text to allow for both formative and summative assessment of their ability to write critically (Winter, 2003). This evolution will be detailed in this practice paper, including the incorporation of Peer Assessment of writing as part of the patchwork text. As a practice paper this cannot be generalised for all engineering disciplines, however as writing is a skill relevant to all, the approach is one that can be adapted by other disciplines.

The original coursework involved a group project on a sustainable energy topic. Teamworking skills are valued by employers (and accreditation bodies), so this important element is still part of the module. However, students can have concerns regarding equal workload and effort by team members, and how this affects their grade (Gunning *et al*., 2022). To overcome this group meetings are scaffolded during class time and at the end of the project there is peer moderation of the grades, which will also be discussed. The incorporation of these peer elements is key in developing graduates' responsibility for their own learning, and the evolution of this approach will be outlined in Section 2.

2 METHODOLOGY

It is widely accepted in higher education that assessment plays a large role in student learning (Fischer *et al*., 2023). Assessment for learning is a key feature of my teaching philosophy building on the use of formative assessment with detailed feedback for the students to reflect on (Nicol & MacFarlane-Dick, 2006). The methodology I developed over the years is outined in this section, firstly describing the module assessment, moving from summative to formative assessment (2.1), then looking at this development of formative assessment using patchwork text and peer assessment (2.2), and then use of peer moderation of group project grades (2.3).

2.1 Module Assessment

The module Energy Management is taught in Autumn to 4th year Mechanical Engineers, it is a 15-week semester: 12 teaching weeks, 1 reading week and 2 exam weeks. The initial Assessment involved a 30% group research project on an energy topic, and a 70% terminal assessment, as outlined in Table 1. The second time I taught this module, this was flipped to 70% continuous assessment and 30% Terminal exam. The terminal exam is solely based on the thermodynamics part of the module, using numerical type exam questions.

The continuous assessment included the group research project as before, now focussed on sustainable energy generation, and the introduction of technical writing assignments; the evolution of which will be discussed in Section 2.2. From 2011 to 2018 an in-class or online mid-term assessment was also used, and the Coursework mark increased to 80% with only 20% for the terminal exam. As shown in Table 1, briefly the Terminal exam increased to 30% in 2019, and has returned to 20%, highlighting how I continuously adapt delivery and assessment of the module. During the Pandemic, when teaching moved online, this assessment mode translated well as it already had a small terminal exam component which was then switched to on online exam.

Table 1 Evolution of Assessment mode 2007-2022

Year	**Student Numbers**	**Continuous Assessment**				**Terminal Exam**
		Group Project	Short Reviews	Final Review	In-class or online MCQ	
2007	74	30%				70%
2010	32	30%	10% (5x2%)	30%		30%
2011	46	30%	15% (3x5%)	30%	5% in-class	20%
2012	46	30%	15% (3x5%)	30%	5% in-class	20%
2014	46	30%	15% (3x5%)	30%	5% in-class	20%
2015	48	30%	15% (3x5%)	30%	5% in-class	20%
2016†	42	30%	15% (3x5%)	30%	5% online	20%
2018	67	30%	10% (2x5%)	30%	10% online	20%
2019	74	30%	15% (2x5%) +5% Peer	25%		30%
2020	68	35%	15% (2x5%) +5%Peer	30%		20% (online)
2021	69	35%	15% (2x5%) +5%Peer	30%		20% (online)
2022	74	35%	15% (2x5%) +5%Peer	30%		20%

*2008, 2009, 2013 on leave, 2017 seconded to Athena SWAN team
† Rubrics introduced

From 2020 there was a slight increase to the Group project mark, which corresponds with the introduction of Peer moderation (as discussed in Section 2.3), and following a brief increase to 30% terminal exam, the overall distribution of 80% continuous assessment was returned to.

For all the written elements Turnitin Feedback Studio (previously known as Turnitin Grademark) is used to provide feedback. Up to 2015 the students received marks under several headings using a detailed gradings scheme, with Table 2 showing the scheme for the 5% Short Technical Review. From 2016 this was developed into a set of rubrics for each element (Short Review, Final Review, Group report). This helps scaffold the students' preparation for the given element. Table 3 presents the current rubric for the Short Technical Review, with the marks awarded similar to those presented in Table 2.

Table 2 2015 Grading scheme for Short Technical review (5% but marked out of 20)

	Excellent	Good	Acceptable	Poor	Dreadful
Language style (technical, not colloquial, no rhetorical questions, punctuation, spelling)	4	3	2	1	0
Technical Content	8	6	4	2	0
Introduction, Conclusion (each)	3	2	1.5	1	0
Referencing	2	1.5	1	0.5	0

Table 3 2022 Rubic for Short Technical Review

	Exceptional	Good	Acceptable	Poor	Inadequate
Introduction	Excellent context given Argument/Case to be made is clearly 'signposted'	Good context given Argument/Case to be made is 'signposted'	Acceptable context given Argument/Case to be made is somewhat apparent; Too long/short	Poor context given Argument/Case to be made is not apparent ; Too short	No context provided Argument/Case to be made is not apparent
Language style (technical, not colloquial, no rhetorical questions, punctuation, spelling)	Excellent technical language used, with no colloquialisms, no rhetorical questions. Correct punctuation and spelling throughout	Good technical language used, A *small* number of colloquialisms or rhetorical questions, or punctuation mistakes, or spelling mistakes	Acceptable technical language used; A number of colloquialisms or rhetorical questions, or punctuation mistakes, or spelling mistakes	Poor technical language used; A *significant* number of colloquialisms or rhetorical questions, or punctuation mistakes, or spelling mistakes	Language used is not appropriate for technical report
Technical Content	Excellent breadth of content (appropriate for the length). Clear argument made or position outlined. Excellent support provided for the argument made	Good breadth of content (appropriate for the length). Argument made or position outlined is not fully clear *Or* more support required for the argument made	Acceptable breadth of content (appropriate for the length). Argument made or position outlined is not fully clear *And* more support required for the argument made	Poor breadth of content (not appropriate for the length). Argument made or point is unclear *And* more support required for the argument made	No real content. No argument made or position outlined is not fully clear
Conclusion	Excellent conclusion on the review. Appropriate length for the length of the review. Points made are synthesized well into a conclusion, linking back to the argument signposted.	Good conclusion on the review. Appropriate length for the length of the review. Points made are synthesized into a conclusion, and may link back to the argument signposted.	Acceptable conclusion on the review. Maybe too short. Points made are may not be synthesised into a conclusion, and may not link back to the argument signposted.	Poor conclusion on the review. Too short. Points made are not synthesized into a conclusion, *or* not linked back to the argument signposted.	No real conclusion or conclusion missing. Too short
Referencing	References complete and properly laid out.	Some gaps in references but Reference section properly laid out. *Or* References complete but gaps in reference section layout	Some gaps in references and/or reference layout.	Major gaps in references and/or reference layout.	No references or sources identified for information.

2.2 Patchwork Text

In transforming the module's assessment, I wanted to promote deeper engagement with the topics while also giving the students the opportunity to get feedback on their technical writing skills in advance of writing their Final Year Project report. Patchwork text involves a number of smaller assessments that can be 'stitched together' to give a final piece (Akister *et al*., 2003; Winter, 2003). The first time I undertook this in 2010 I had the students write five short essays, approx. 250 words each, for which they received marks (a small 2% max) and more importantly feedback, and they could choose whether to use these as part of their final essay. The grading load involved was too high, so from 2011-2016 this was changed to three 5% pieces. The students submitted their first essay early in semester, this is graded using the rubric and returned to them before they prepare the second one, and same then for the third; with the aim that these short essays, once reworked based on the feedback, would form the Introduction to the final essay.

Due to engineering student resistance to writing 'essays' the assignment was retitled to *Technical Review*, and the expectation is the writing style is that of a Literature Review. Regardless of what it was called, it was clear from the improvement in the quality of work submitted, and grades attained, that student engagement with the topics increased – leading to deeper learning, as also evidenced by Trevelyan and Wilson (2012). The students' ability to think and write critically was scaffolded by the use of the short reviews and the feedback they received, to help them prepare the longer Technical Review. Their appreciation of this approach has been noted in module feedback, and also in end of year feedback to External Examiners. The introduction of rubrics in 2016, as discussed in the last section further aided in the development of these critical writing skills, as they know before they write what is expected at all levels for all categories under which the piece will be graded.

In 2018 the class size increased by over 40% as shown in Table 1, which meant that the grading workload was too onerous again. Initially in 2018 the short reviews were cut from three to two per student. In 2019 to try ease the workload issues, but also to try develop better critical thinking skills in the students, I decided to involve the students in the grading (Moloney *et al*., 2019). Peer assessment has been shown to robust and is supported as a formative method (Double *et al*., 2020).

The practice since 2019 involves the students each anonymously reading and grading two other reviews using the rubric, after which they must do a self-review. A limitation to this approach is that it is dependent on students engaging with the peer-assessment. To encourage them to do this, they get up to 5% for giving these reviews. Better engagement will get the full 5%, and while this may seem like an 'easy' 5%, feedback from the students in module evaluations and in their self-reviews shows that they find it very useful to see exemplars of their peer's writing. From their reflective self-reviews students have indicated that they find the peer-review very useful in helping them understand how to correctly frame a review – from language style to forming a cohesive argument. Students may distrust peer assessment (Planas Lladó *et al*., 2014), so it is imperative to discuss their responsibilities in advance of the peer assessment. The reliability and validity of the peer assessment is monitored to ensure the marks and comments are appropriate.

While this is a relatively smaller cohort, averaging 70 students, Power and Tanner (2023) have suggested peer assessment is appropriate to use with even larger cohorts with suitable use of a Virtual Learning Environment (VLE) to assure anonymity.

2.3 Group Project - Peer moderation

The group research project has been a key assessment tool in this module, since before I started teaching it. Initially each tutorial group had 15 students per hour, and in five project groups of three students they researched an energy topic of interest over the first 3-4 weeks of semester and then over the following weeks they took turns to give a 30 min presentation. In 2007 for many it was their first time giving a formal presentation, which has since changed with curriculum development. The group research project was timed so that the group presentation took place early in the semester in advance of Final Year project Interim presentations. As there were different dates for presenting, each group then had two weeks to submit the written report. As detailed in Section 2.1 from the start Turnitin Grademark has been used to allow detailed feedback on the report. With VLE enhancements regarding group submissions this has become more straightforward in the last five years. These research projects serve to significantly improve their knowledge in a particular area of sustainable energy and also develop their awareness of other topics, though attendance at the presentations.

Overall this structure has worked very well and there have only been a few changes over the years. As noted, the grading workload is quite substantial, and due to increasing class size in 2020 the groups were increased from three to five students to reduce the number of projects to be graded, with 30 students in 2-hours, allowing six groups of five. In 2021 & 2022, instead of being spread from weeks 4-8, more time was given to project scaffolding in the tutorials, with all presentations occurring between Week 7 & 8, and the Final report due for all in Week 9.

There are student and academic concerns regarding group work and ensuring that those who do the work are rewarded accordingly (Gunning *et al*., 2022). Especially in 4th year, students can worry that their grades and final awards will be impacted, yet the ability to work in a team is a key Programme Outcome for Engineer's Ireland accreditation. Initially for this module each group had to declare how the final mark would be allocated, and when the groups were smaller it was easier to distinguish if the group mark needed to be moderated to reflect the individual workloads. With increased numbers in each group, managing these dynamics became more difficult. In 2021 I introduced the use of an individual online form (using MS Forms) based on a small subset of WebPA criteria (Loddington *et al.*; 2009) where each student rates themselves and their group colleagues under five personal effectiveness criteria, as described in Table 4. If work was shared equally amongst the group, then they are asked to choose 'about average for this group' for all, including themself. The scores for each student under each criterion are averaged, and this has led to more robust peer moderation of the group grade. If any group feels the moderation does not fully reflect the workload, then they are free to discuss this, but as of yet there have not been any issues. Again, module feedback has shown that students value this way of being able distinguish those that have do more work to make up for others.

Table 4 Peer moderation of individual effectiveness (adapted from (WebPA, 2019)*)*

Criteria	Description
Co-operation	attendance at meetings, contribution to meetings, carrying out of designated tasks, dealing with problems.
Communication	effectiveness in meetings, clarity of work submitted to the group, negotiation with the group, communication between meetings and providing feedback.
Enthusiasm	motivation, creativity and initiative during the project
Organisation	Self-organisation and the ability to organise others, including planning, setting targets, establishing ground rules and keeping to deadlines.
Contribution	Overall effort put in by an individual during the Project (Weeks 1-9)

3 SUMMARY

The pivot to online teaching and learning in 2020 and 2021 highlighted that terminal assessment is flawed, especially when the assessment is online and not proctored. In the return to on-campus teaching it is important not to lose the best practices of using increased Continuous Assessment. Taking an ‘Assessment for Learning’ approach, a number of different strategies are used in this module.

- The use of Patchwork Text develops the student’s critical writing skills, though use of timely feedback that can then be used to write their final review.
- Including an element of Peer review in this Patchwork Text structure has been shown, through module feedback and student self-review comments, to also accentuate their understanding of good technical writing, as they see other people’s writing (good or bad) and it obliges them to engage with the rubrics that are used for the assessment.
- Acknowledging the concerns that students have with group project work, the use of peer moderation forms allows for them to acknowledge how the workload was shared, and again from student feedback this has been welcomed.

This paper is intended as a practice paper, to show how my practice has evolved and how I attempt to develop deeper learning and utilise peer elements to foster graduates’ responsibility for their own learning. Over the last two years, following the staged return to on-campus teaching there has been a noticeable change to the level of student engagement. Methods such as these – patchwork text and peer assessment, group work and peer moderation – can assist in motivating a responsibility for their own learning. While the methods are not applicable to all, there may be elements that can be adapted for other’s teaching.

A principal factor of my approach is to move away from the standard high stake terminal exam, that is used by many as it is an efficient way to assess. The approaches I have discussed show a way that a Module Leader can sustainably move to more continuous assessment. This is applicable for all engineering studies, not only the ‘softer skills’. A limitation of this study is that the feedback is all based on module feedback and student self-review, therefore further structured research of student perceptions is planned.

ABSTRACT

The ERASMUS+ European University for Well-Being (EUniWell) alliance's mission aims to resolve the paradox of Europeans' relative prosperity against the global security and sustainability challenge. "Maximising Academic and Social Outcomes in Engineering Education" is a project which interprets this contradiction for engineering

[1] *NJ Cooke*

n.j.cooke@bham.ac.uk

educators; how to best teach non-technical skills to ensure engineers make the utmost contribution to societal wellbeing? Appreciably, the social outcome for the person who becomes an engineer is positive because the profession is relatively well-paid. Therefore, engineering education is good for social mobility providing the learning environment narrows attainment gaps between disadvantaged and mainstream cohorts. Accordingly, our strategy is to bring together the expertise of the British, French, Italian and Swedish faculties to transfer best practice for professional, business and sustainability skill teaching, while contrasting how their disadvantaged cohorts present. The project has two primary objectives: To understand how partners differ in terms of skill teaching, and how students from disadvantaged backgrounds are accommodated. The paper describes the background and rationale of the project, and its research design and methodology. Although the project is still in progress and data collection is still underway, this paper provides insights and perspectives for engineering educators looking to design similar collaborations to share best practice, while considering engineering identities and their underlying competencies.

1 INTRODUCTION

Engineering is known to have a distinct cultural identity, which encompasses solving well-defined problems through the development of products, processes, and services. This identity is formed throughout the student's period of study. However, if the focus is solely on developing more practical skills, the question arises as to whether the students are developing holistically; What role do other professional skills have in developing students as engineers? It is our position that currently professional skills, such as innovation, enterprise, and creativity; communication and networking; and social, environment, and technical responsibility, are more subjective and subsequently are not taught as well by faculty. As a result, there are negative social outcomes in terms of satisfaction and wellbeing, despite the student successfully meeting any programme's learning outcomes.

The broader EUniWell alliance mission is to resolve the paradox of Europeans' relative levels of prosperity against the global challenges in society they face: health, environment, political instability, and defence. Maximising Academic and Social Outcomes in Engineering Education (MASOEE) interprets this contradiction for the engineering profession as how to best teach the non-technical skills to ensure engineers make their utmost contributions to societal wellbeing. Our strategy is to bring together the expertise of Birmingham, Florence, Linnaeus, and Nantes engineering faculties to share and develop expertise to improve the social outcomes of engineering students.

The cultural identity of professional engineers is often dominated by practical skills. Therefore, a key aim of the project is to explore ways in which we can 'rebalance' the education of engineering students, ensuring that there is as much emphasis on professional skills as there is on practical. The rest of this paper is as follows. Section 2 provides some theoretical background behind the project; section 3 describes the research methodology; section 4 some preliminary results and section 5 a summary.

2 BACKGROUND

Engineering culture has traditionally focused on technical competence, such as the basics of science and mathematics, design, and analysis skills, as well as the use of engineering tools and methods, which produces a ‘traditional technologist’ (Berge, Silfver, and Danielsson 2019). However, as these authors note, most contemporary faculties dealing with the education of engineers have moved away from this narrow focus and towards incorporating other skills such as professional skills, enterprise, and sustainability and ethics. It is because of this shift to a more contemporary approach, that they suggest that three new engineering identities have emerged: ‘Self-made engineer’, ‘Contemporary technologist’, and ‘Responsible engineer’.

‘Social-technical’ dualism (Faulkner 2015) is the separation of ‘technical’ skills and ‘social’ competencies. It can often be reinforced through both the design and delivery of the curriculum and can subsequently lead to a ‘hidden curriculum’ (Tormey et al. 2015), typically comprising separate learning units for skills which are delivered by non-engineering experts. This results in non-technical competencies being duly taught and learned, but not widely thought of as an engineer’s problem, and thus not fully integrated into day-to-day engineering habits. Our project is designed to not only understand both staff and student attitudes to these skills, but also to identify how this hidden curriculum manifests.

The global marketplace in higher education and its neoliberal trends, where students are customers, and where higher education is expected to produce employment-ready graduates, leads to social outcomes in education being considered chiefly through graduate destinations and earning potential (Berg, Huijbens, and Larsen 2016). As engineering is a relatively well-paid profession, the ultimate social outcome of studying engineering and then entering its profession for the individual can be considered net positive. For this reason, engineering education can be a force for social mobility, especially when faculty make a conscious effort to widen access for disadvantaged students. Consequently, once they arrive on campus, the learning environment delivers and equitable education which narrows any attainment gaps between disadvantaged groups and the mainstream cohorts. MASOEE partners have different definitions for what is considered a disadvantaged student in this context, and consequently what interventions they practice to narrow attainment. Therefore, understanding these differences and how students from these backgrounds experience the process of becoming an engineer and the types of intervention that make a difference is a valuable knowledge exchange.

3 METHODOLOGY

3.1 Research questions

Reflecting on this background, we have formulated the following research questions:

- What are the similarities and differences between engineering partners, their student bodies, teaching, programme structures, and institution culture?
- How are the skills currently taught and embedded in programmes? What are student attitudes to learning these? How do we currently define and measure social outcomes?
- Which new approaches can we employ to better teach these skills that deliver better social and academic outcomes?

Fig. 1 provides an overview of the project, illustrating how the different components contribute to developing a comprehensive understanding of the teaching of professional skills within the partner universities, as well as how the partners are widening participation of disadvantaged students, ultimately narrowing any potential attainment gaps. The project is comprised of four 'Work Packages' (WP1, WP2, WP3, and WP4). WP1, WP2, and WP3 are designed to collect data, offering practitioner workshops and general data collection opportunities. WP1 concerns innovation, enterprise, and creativity; WP2 concerns communication and networking; WP3 concerns social, environment, and technical responsibility. WP4 is utilised to co-ordinate overall engineering education research approaches and research questions, as well as general project management.

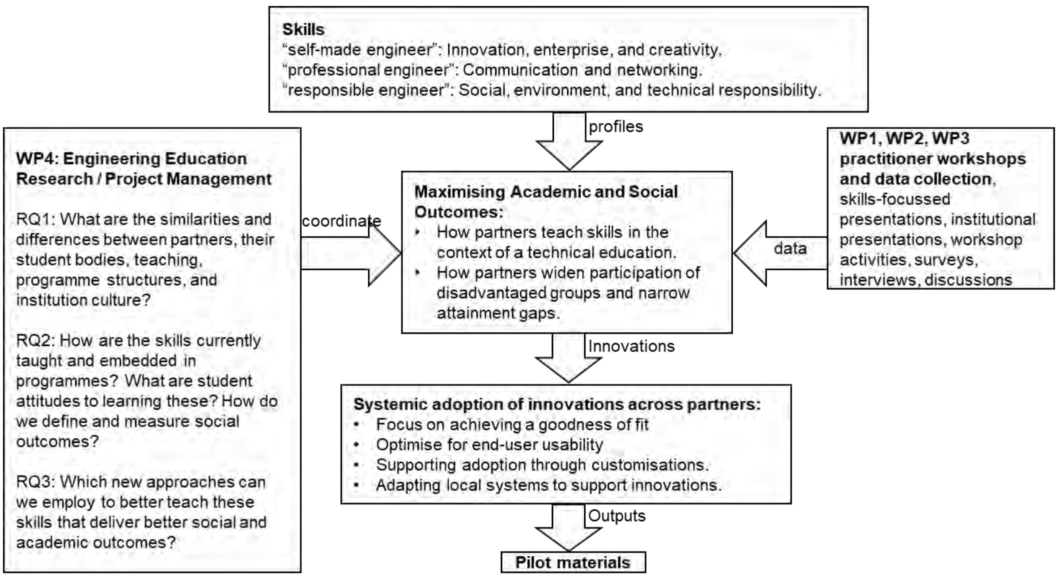

Fig. 1. Project workflow.

3.2 Mapping engineering identities to skill taxonomies

So that all partners share a common definition for discussing the skills sets, the project will draw on existing skill inventories and taxonomies and map them to the 3 engineering cultures defined by (Berge, Silfver, and Danielsson 2019) as shown in Table 1.

Table 1. Engineering identities mapped to MASOEE skill mappings

Engineering identity as defined by (Berge, Silfver, and Danielsson 2019)	**MASOEE skill mappings to frameworks**
Traditional technologist (status-quo)	Science and maths, design, analysis, engineering tools and methods.
Self-made engineer (neoliberal trends)	WP1 Entrepreneurship: Innovation, enterprise & creativity Entercomp (Bacigalupo et al. 2016)
Contemporary technologist (progressive trends)	WP2 Solving complex challenges: Communication & networking. WEF 21st Century Skills (Soffel 2016)
Responsible engineer (sustainability trends)	WP3: Sustainability competence: Technical, social & environment responsibility. EU GreenComp (Bianchi, Pisiotis, and Cabrera Giraldez 2022)

3.3 Mixed methods

(Johnson and Onwuegbuzie 2004a) argue that it is the diverse nature of mixed methods that results in higher quality research. The MASOEE project strategy is to examine the similarities and differences between institutions in terms of student bodies, teaching, programme structures, and institutional culture. Whilst it is possible to gather some of this data within a quantitative manner, exploring student attitudes needs a more qualitative approach, leading to the decision to adopt a mixed method research design. To help understand how this mixed method research has been structured, the research questions were broken down into each method used to help answer it and whether it is qualitative or quantitative (Table 2).

3.4 Survey

The survey was designed to obtain an overview of current professional skills teaching practices, similarities and differences between the different partner universities, and demographics (current year of study, foundation/pre-year, discipline, University, country of birth, country they attended secondary school in, measure of disadvantaged status). Each partner shared how disadvantage was monitored within their own country. Whilst there was some crossover between the partners in terms of how they monitor disadvantaged status, there are also some differences (Fig. 2).

3.5 Documentation, interviews, and focus groups

The qualitative aspect of the research encompasses documentation, interviews, and focus groups, which explore attitudes and approaches, and will build on information found within the survey phase. Interview and focus group schedules were developed to guide the process. In terms of document analysis, the team created a curriculum grid, entering information on modules that are running at each institute.

Table 2. Research methods identified to answer research questions

3.6 Case study documentation: best practice adoption across partners

MASOEE partners exchange best practice through sharing case studies. Moreover, to facilitate integration of new practice into their institutions, the case studies are structured drawing on the literature of diffusion of innovations – notably the propagation paradigm (Froyd et al. 2017) where the key object is to maximise the efficacy and the fit to the partner to allow for meaningful adoption. The characteristics of this propagation paradigm include: The focus being fit rather than evidence of efficacy. This requires dialogue with partners for how to adapt an innovation at a partner; The innovations should be characterised by usability to provide generalisation to other settings, rather than strong data; Partner interactions through case study presentations ought to support adoption rather than raise awareness; The different instructional systems of the partners e.g., Canvas, Moodle, must be considered as part of the case study so that technical frictions can be reduced.

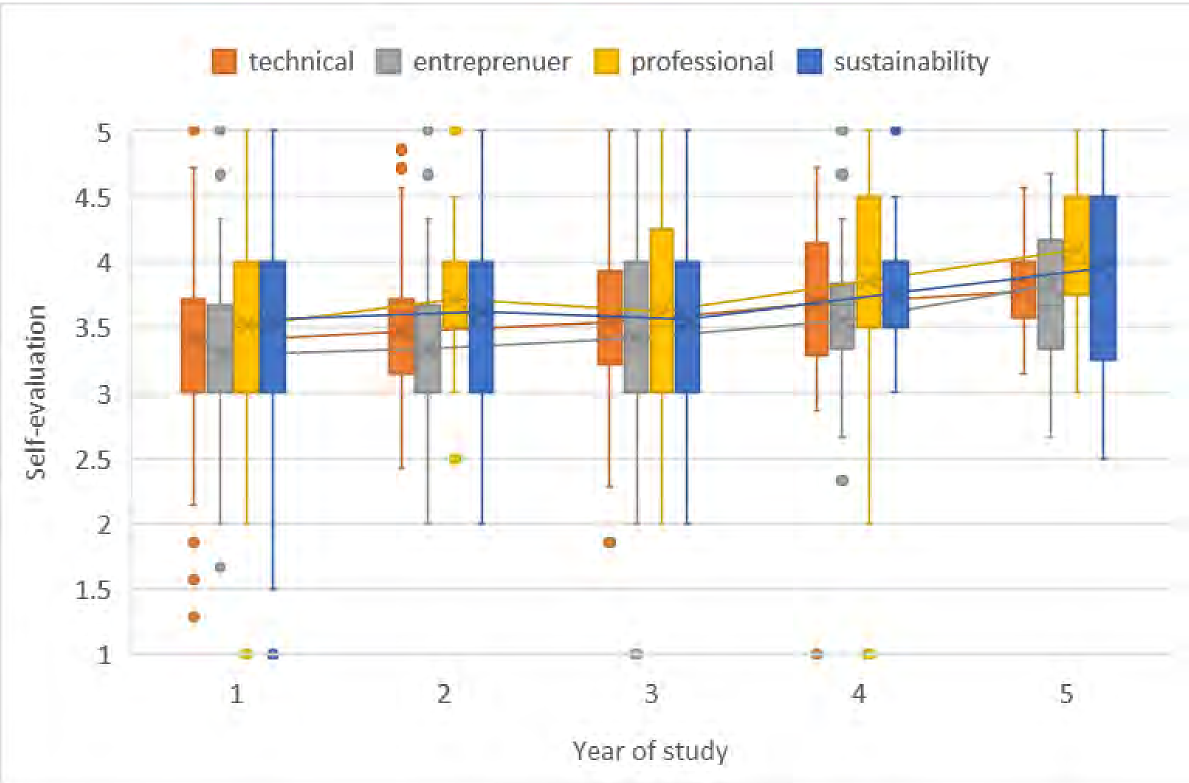

Fig. 2 Self-evaluation of MASOEE skill mappings against year of study (n=535)

4 PRELIMINARY RESULTS FROM SURVEY

As outlined in Table 2, a student survey is being conducted by all partners. The survey has been translated into the language of each partner's country and captures demographic information as well as attitudes to teaching skills and student self-rating of abilities in each of the skill sets outlined in Table 1. Early results highlight differences in students' self-evaluation of the MASOEE skills mapping they are learning; e.g. for one partner's cohort (Fig. 2) where we compared skills against year of study, we observe that there is a gradual upward trend in most skill levels with some difference in variances between year. Although further analysis is needed, there are a couple of stand-out results that are driving our focus group and interview discussions: Sustainability skills (blue) are fairly consistent from years 1-3 but increase in years 4-5. Entrepreneurship skills (grey) follow a similar trajectory although in the first 2 years there is a greater concentration of students rating themselves as lower, resulting in a smaller variance. Going forward, it will be interesting to compare institution’s cohorts and differences and relate these to their curriculum and culture.

5. SUMMARY

Accreditation standards and a globalised engineering educator profession can bring about harmonization of European engineering degrees. However, we enjoy different cultures and contexts, including student and staff diversity, language, national priorities, facilities, exchange opportunities, and industry collaborations. The MASOEE project is a creative learning process to share this knowledge and expertise.

ACKNOWLEDGEMENTS

This project is funded by ERASMUS+ 2020 EUniWell Alliance.

Keywords: *decolonization, self-concept, metacognition, teamwork, retention*

ABSTRACT

The proportion of early leavers from engineering degrees closely follows the higher education sector throughout Europe; around 10% leave before graduation. Students are more likely to drop-out if they do not feel that they belong in the learning community. While research shows that academic achievement is a primary factor contributing to student drop-out, other student-centric social factors, such as belonging are equally important to student drop-out rates within higher education. The aim of this paper is to present a model constructed on student belonging. The model consists of 3 pillars, namely academic self-concept & professional identity, psychologically safe teamwork, and decolonisation. The study was based on the development and continuous refinement of interventions that could assist students with feeling a sense of belonging. While the primary intention of this project is to present a body of work that highlights belonging as a contributing factor that may be pivotal to a student remaining in higher education or dropping out, readers will also learn about how best to support students in gaining a sense of belonging through self-concept, providing safe teamwork and by decolonising the curriculum.

1 INTRODUCTION

A loss of human capital and talent for the engineering sector is a potential outcome of high student attrition in engineering degrees - the number of students who leave their programmes before completion. This exodus compounds the STEM skills shortage reported across many industry sectors. Around 8% of UK students leave university during their first year of study which is replicated elsewhere in Europe where 11.4% of men and 7.9% women in 2021 are early leavers (European Commission 2022). However, often, the situation in engineering faculties is reported higher than their university-wide averages (Andrews, Clark, and Phull 2020).

There are many factors identified in the literature since the 1970s as to why students leave early, and indeed many strategies suggested as to what universities might do to keep them. In (van den Bogaard 2012)'s review of this literature and its applicability to the engineering education context in the Netherlands, several frameworks are analysed identifying these factors. Broadly speaking, most factors are student-centric including background such as age, disposition e.g. motivation, and behaviour e.g. time commitment. Contrastingly, the education setting contributes to attrition through several factors including structures, pedagogies, and how students and staff interact. Although this review finds that the single most consistent and stable predictor of retention is students' ability, it makes the important observation that student abilities are influenced by the education experience we deliver.

So how do we change our educational settings to improve students' abilities and thus reduce the dropout rate? In this work we propose a model to improve students' sense of belonging. This choice is not casual, as belonging has long been established as a success factor which indeed might be inhibited by an over-representation of introverted students in engineering (Wilson, Spring, and Hansen 2008). Our work focuses on three pillars: academic self-concept, psychologically-safe teamwork, and decolonisation. We developed this work by integrating several ongoing studies across the University of Birmingham in the United Kingdom (UK). This is a research-focussed university with approximately 5000 engineering students across 6 faculties and a student cohort roughly split equally between international and home students. We recognise that different students and faculties may have different needs and challenges. Indeed, there will be other factors beyond our control that affect student success such as their personal circumstance, health, and finances. However, we believe that by focussing on these three pillars, we can enhance the education for all students.

2 THE MODEL

The primary factor for students leaving university may often be related to students' academic achievement (Greenland and Moore 2022). Decades of research have been dedicated to innovative pedagogies to improve student success. However, a more holistic approach may be necessary as good academic results may not be the only factor contributing to the drop-out rates.

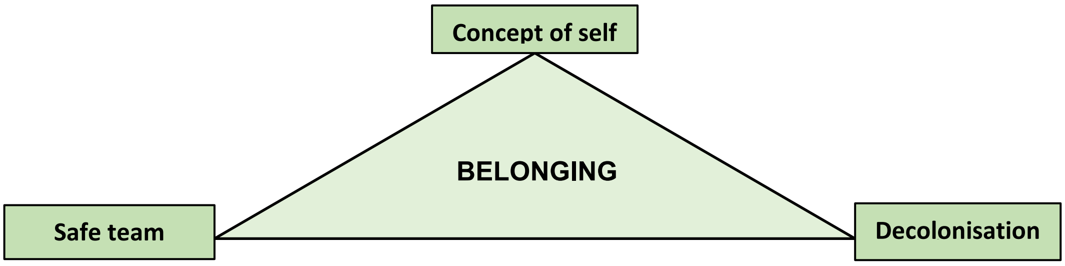

Fig. 1. Belonging model.

For this study we have identified belonging as one of the key factors to students' wellbeing, contributing to whether student successfully completes their degree. We propose a model (see Fig. 1) that underpins student belonging to reduce or prevent early leavers. The model consists of 3 pillars, namely decolonization of the curriculum and of teaching and learning practices, academic self-concept, and psychologically safe teamwork which together provide a foundation on which a sense of belonging can be built. This study was designed and implemented to address the different pillars of the model.

We address academic self-concept & professional identity – a person's belief about their abilities, role, and purpose – since it is likely to be lower for under-represented student groups because of the reciprocal relationship with, and interpretations of, their environment. We discuss our development of teaching interventions to better develop metacognition and self-regulation to raise self-concept. Psychologically safe teamwork – where all members are comfortable and perform optimally - is an area that many students struggle with. Several suggestions explain the difficulties in group dynamics such as language differences, cultural incompatibility, social skills, and individualistic competition. We outline how cultural differences are being supported through early interactions within a group setting to offset many of these issues. Decolonisation – teaching engineering in a way that is fair and effective across ethnic, racial, social and cultural perspectives - is widely considered essential (Bhambra, Gebrial, and Nişancıoğlu 2018) yet challenging for STEM, with a disproportionate effect on minority students which itself risks damaging the cohesion of entire cohorts. It is crucial to shift the conversation, through appropriate research, from "why decolonise?" to "why not?", and we describe how this research can be developed into educator trainings to help demystify the term.

3 SELF-CONCEPT

The first aspect of our model is to understand how students see themselves. We are undertaking 3 projects in this area focussing on academic self-concept, professional identity, and metacognition respectively.

3.1 Academic self-concept for foundation year students

Academic self-concept (ASC) refers to a student's own evaluation of their academic abilities. It is frequently indirectly referred to with other names such as self-reported grades. In a recent study based on a longitudinal dataset of children in the UK born 1989/1990, the authors found that students with higher ASC were more likely to progress from compulsory, through to non-compulsory then higher education, and that these findings were applicable in all subjects including engineering (Marsh and O'Mara 2008). Although the study did not look directly at the relationship between ASC and retention once students reached higher education, based on ASCs correlation with positive trajectories in education, it is reasonable to assume that this continues during higher education.

To investigate ASC in our context, students enrolled on the foundation year programme were invited to complete a survey of ASC in their first month on the programme. The survey tool used was the Academic Self Concept Scale (ASCS) (Reynolds 1988), a 40-item Likert-scale survey with questions such as "Being a student is a very rewarding experience", "No matter how hard I try I do not do well in school" and "Others view me as intelligent". Items are scored between 1 and 4, so the metric mean is 2.5. 149 students were invited to complete an online ASCS survey. 33 responded demonstrating a range in ASC between 2.05 and 3.50 with a cohort mean of 2.71 for respondents.

To improve ASC scores, we have introduced a 'Guided Study' in the academic year 2021-22 with the aim of developing student belonging by providing opportunities for peer supported learning and structured yet informal contact sessions with at least two academic staff. The goal is to create the opportunities described above to facilitate informal interaction between students and academics, and to support students in developing peer relationships and their own ASC building on the principal that transition to university activities ought to be student-centred and provide informal opportunities for relationship building (Briggs, Clark, and Hall 2012).

Informal feedback from students indicated improved scores, and in future we hope to demonstrate more improvement as a result of engagement with interventions building on Guided Study.

3.2 Professional identity framework for student years 1-5

Complementing the ASC for the foundation year students is concept of Professional identity which we consider for all subsequent years of study. The Cambridge dictionary defines identity as "who a person is, or the qualities of a person or group that make them different from others". In engineering education, students' engineering identity affects their performance and career choices. Engineering schools can use this concept to understand their students, widen participation, and improve career outcomes (Hansen, Henderson, and Shure 2023).

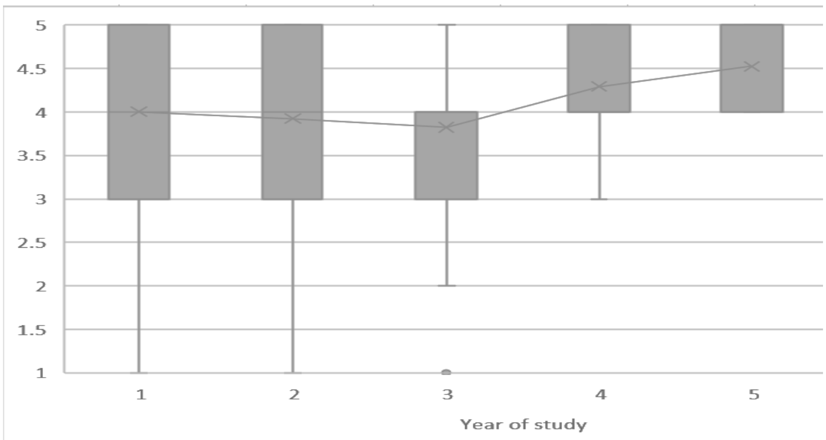

Fig. 2. Distribution of students (n=506) self-concept of identifying as an engineer

We developed a professional identity framework to help engineering faculty to improve their programme development, module designs, and motivate students' skill development and inform their career choices (Cooke and Hawwash 2020). The framework has a survey instrument embedded into the yearly academic review process that measures ASC by getting students to evaluate themselves against the full skill inventory. As a broad measure of identity, one survey question asks how much they agree with the statement "I identify as an engineer" on a 5-pt likert scale. We analysed this response for 536 students in electrical, civil, and mechanical disciplines against their year of study in 2022/23. We found a slight decrease in the average score between from year 1 (4.0) to year 3 (3.8), but then an increase for year 4 (4.3) and year 5 (4.5) (Fig. 2). This trend might be explained by the fact that a proportion of students leave at the end of year 3 with Batchelors degrees, while those who continue in years 4 and 5 are studying for at Masters level, which leads to them developing a stronger identity as engineers. We are further analysing whether this trend can help identify students who might be prematurely leaving with Batchelors degrees with lower than average ASC, despite having the capabilities to complete engineering study as Masters level.

3.3 Metacognition to improve self-concept

ASC requires students to reflect on their experiences and be effective learners. These skills are more formally referred metacognition and self-regulation. Developing metacognition and self-regulation are optimal skills that students should acquire to mature academically because students who can reflect on their thinking perform better academically. Being able to critically think about one's own learning process is vital for students to develop their own ASC and professional identity, especially in an environment where they may not have the experience or support that more established students might have. Acquiring such skills means that students can analyse their learning; determine whether their understanding of it is true; and develop a feedback mechanism with which to constantly evaluate the quality of their learning. This may lead to a more positive academic experience overall.

Furthermore, metacognition is a crucial part of developing an academic concept of self. Over the past 3 years (2020/21 to 2022/23) a project is underway within the School of Computer Science (SoCS) to evaluate the effects of applying metacognitive skills in an undergraduate and post-graduate curriculum. From 2020/21 academic year programming modules taught to both cohorts, included several tools to assist them with acquiring metacognitive skills and therefore being able to reflect on their learning. This was particularly important during Covid when students' learning was fully online. Although a blended learning approach has been adopted post-Covid, the use of these tools has been maintained. For example, the use of Kahoot is an effective tool for both educators and students to reflect on their teaching and learning (Altawalbeh and Irwanto 2023). Within a classroom environment, regardless of class size, educators can instantly be provided with feedback on how students are performing. Conversely, students can measure their own learning.

Currently, students complete a weekly reflective online survey that prompts them to think about their understanding of the content; lab work and tutorials completed; other formative assessments; and their level of engagement with the content. The survey provides students with a score, then if their score is below a particular number, further suggestions on how to improve their learning are offered. Current data collection for 2020/21 to 2022/23 shows that although students initially engage with metacognition thinking tools, they very quickly then disengage. For example, engagement dropped steadily from 349 students in the first week of class to a mere 7 in the last week of class and averaged only 75 students per week.

However, research shows that when a tool is fun students tend to continue using it (Licorish and Lötter 2022). For example, Kahoot quizzes were also presented to students weekly (throughout the same academic periods), and while engagement fluctuated more, it remained high every week with an average of 244 students applying the tool. One further difference between the implementation of the two tools mentioned above is that the Kahoot quizzes were run during class time, while the Canvas quizzes were available to the students at any point during the week.

From these results the following points of interest become apparent: metacognition, while intrinsically a solitary activity, is enhanced by the support of academics and peers; secondly making the process of metacognition more fun results in higher engagement. By making the tools for metacognition, and the skills to use them, more easily available to all students, those students who might not have a well-defined academic concept of self, have an opportunity to improve this concept of self.

4 PSYCHOLOGICALLY SAFE TEAMWORK

Whereas the self-concept pillar of our belonging model helps students to develop individually, the safe teamwork pillar focuses on their relationships; we want all students to feel secure and confident when collaborating. In many engineering programmes including ours, home students perform better than international students. This is not just because of language skills, as our data from our postgraduate Master’s courses shows; the attainment gap exists even when international students studied in English for their first degree. We aim to identify and close this gap.

For pedagogical benefits, increasing amounts of study time are spent in groupwork. International students frequently achieve a higher grade in group assignments when compared to their individual work demonstrating the power of diversity (Channon et al. 2017). However, they also face challenges, particularly when groups are mixed between home and international students (Baker and Clark 2010). These challenges include communication, lack of group work experience, different expectations and cultural norms. This pillar aims to improve students' performance by modifying group structures, assignments, and staff and student training on group work skills. The first stage of this is to observe groups working together and identify if any of the issues highlighted in academic literature are present. A group of 58 students (32 international) were observed working on a series of challenges relating to systems engineering and ergonomics during an intensive module week. Groups or 6 or 7 were allocated randomly and students were expected to organise team roles themselves.

We observed that in all groups a home student became the leader and allocated duties. The exercise briefs allowed for solutions geared to international audience, yet groups usually focussed on the home student preference; home students often gave opinions first and led the group in their preferred direction. Home students took on a parent/teacher role, with international students asking questions. After the first day a number of international students did not return to the group sessions. These observations have led to our questioning the structure and content of all groupwork that is completed by students; group dynamics will be affected by the exercises students are asked to complete e.g. if an exercise can be completed by one or two students then home students have less incentive to involve international students, particularly if there are perceived communication barriers. Moreover, a project based in UK industry puts international students at an immediate disadvantage and are less likely to lead.

The next step in this work is to change these group dynamics and make group work psychologically safer. We are encouraging staff to consider cultural differences to make group exercises more inclusive, better contextualising tasks to several countries. This way, international student's knowledge becomes valuable to the group. Furthermore, we are improving teaching of interpersonal skills and how other cultures communicate.

5 DECOLONISATION

This pillar focuses on decolonisation's contribution to students' self-concept, attainment gaps, and their interaction. Evidence shows persistent gaps in attainment for underrepresented groups. Widening participation processes have been broadly speaking successful in the UK Higher education systems, but gaps persist at the award level especially between BAME and white students.

To address persistent gaps in attainment for underrepresented groups, decolonising the curriculum is necessary. This involves recognising and addressing the legacy of disadvantage, injustice, and racism. Curriculum decolonisation covers all aspects of learning, but focusing on student perceptions and relationships is especially fitting in our model. We commissioned a study in 2020 to explore academic disparity, also known as the "ethnicity attainment gap" (Rana et al. 2022). The study aims to investigate student perspectives and perceptions on this topic and offer strategies to tackle them. The results indicate that it is crucial to cultivate a stronger sense of belonging among students, both with their peers and with staff members. We found that fostering a sense of belonging is an important first step towards achieving the necessary cultural and behavioural changes to close this gap. Other researchers also consistently find a sense of belonging is linked to success e.g. (Pedler, Willis, and Nieuwoudt 2022).

While acknowledging that the causes behind the academic disparity are highly complex (Stevenson 2012), our study's key finding highlighted that only 37% of BAME students surveyed felt a sense of belonging, compared to 83% of white students. Despite accounting for multiple socio-economic factors and previous academic achievement, questions remain that can be effectively addressed by exploring students' beliefs about their potential. Stevenson's research revealed that many minority ethnic students have internalized negative stereotypes associated with their ethnic group, which may lead to self-doubt, underachievement, and a mismatch between their perceived and possible future selves. One notable difference between the attitudes of BAME and white students in both studies was their intentionality in contacting academics for support. Interestingly, this is not due to fear of discrimination, but the students' perception of their own self-worth and the likelihood of establishing meaningful dialogue with staff members. This is clearly represented by the fact that a minority of BAME students find their lecturers approachable, compared to the majority of white students surveyed.

Despite the complexity of the problem and potential solutions, it is crucial to openly address race and ethnicity, particularly in STEM subjects, where the debate is lagging behind. Decolonizing education involves bringing these issues to the forefront of student experience design and evaluation, ultimately promoting a greater sense of belonging and improving educational and social outcomes. In this context, there are three areas of focus for intervention: promoting a sense of belonging, improving staff/student relationships, and increasing staff diversity, especially in leadership roles. We plan to investigate student belonging within their academic community, considering the impact of Covid since our 2020 study. Additionally, we will examine staff perceptions and attitudes.

6 SUMMARY

“Engineering student belonging” aims to improve student success through integrating and developing measures and interventions that focus on self concept, safe teamwork, and curriculum decolonisation. In this paper we have raised awareness of several of its foundation projects to inform training of educators and the development of teaching interventions.

ABSTRACT

The ability to use scripting tools to harness the power of complex engineering software is not only critical for research and industry, but also offers opportunities for student learning and development. This paper covers two ways in which undergraduate engineering students have been exposed to Ansys simulation tools to be controlled from Python programs. A pilot series of 'CodeFests' have been held in partnership with university engineering departments, offering a fun way for students to engage with Python coding while exploring the power of scripting to optimise or iterate on solutions. These have used the PyMAPDL structural simulation library, leveraging students' existing understanding of mechanical engineering problems to provide a 'way in'. Students tackled simple mechanical challenges, but with a twist – such as an optimisation requirement which would be beyond manual ability to solve in the time available. In parallel, the potential for scripting tools to provide 'lab in a box' type experiences harnessing the most powerful simulation tools has been investigated. A basic prototype to replicate a fluids lab exercise involving a cylinder in a wind tunnel was created inside a Jupyter Lab running Ansys Fluent through the PyFluent library. This provided a simple, customizable way for students to interact with a 'lab' powered by simulation, without needing to teach them the Ansys Fluent interface and controls first. Both these projects show the potential for harnessing simulation power further in engineering education through scripting methods, to engage and empower the engineers of tomorrow.

1 INTRODUCTION

1.1 Scripting Tools and Simulation

Many engineering software tools are designed with specific purposes or specific user groups in mind, which can limit their functionality for other user groups or for people who wish to use them in combination with other tools. The ability to use scripting tools with software, however, opens up a much wider variety of possible use cases, and creates opportunities for both research and teaching.

Since 2020 [1], Ansys has been releasing 'PyAnsys' libraries, which are an Open Source set of technologies that allow users to interface with Ansys solvers such as MAPDL (Mechanical), Fluent (Fluids) or AEDT (Electronics) from an external Python environment. This then allows users to connect these solvers and their outputs to the richness of tools in the wider Python ecosystem.

The value of this in a research or commercial engineering environment is clear, and PyAnsys is already being used in research groups to couple Ansys simulation software with optimisation routines, machine learning algorithms and more [2], [3], [4]. However, an opportunity also arises to deploy these tools within the undergraduate engineering curriculum, where other benefits could be found.

1.2 Motivation

As a leading simulation software company supplying software across a wide range of industry sectors, we at Ansys are aware of the needs of students as they enter the work force when it comes to software tool understanding, etc. But there is evidence that there is a large gap between what industry expects from new graduates and the curriculum students are being taught [5], [6], [7]. One skill in particular that has been highlighted as necessary for the next generation to have is experience with industry-level software [5]. Based on understanding of the value coding and simulation have in industry, and the possibilities which arise from combining the two we have been piloting potential academic-industry engagement in this area in two ways: organising 'CodeFests' and investigating lab work using Jupyter Notebooks and simulation.

1.3 Practice Undertaken

This paper explores two different ways of exposing students to scripting tools: firstly, as a tool for them to explore themselves, enhancing their skillset, and secondly, as an enabling tool to allow introductory students to benefit from advanced software they might not otherwise use.

A pilot series of 'CodeFest' events have been held at a small number of universities, giving students team challenges to tackle by writing their own code leveraging Ansys simulation software. The purpose of these events was to expose students to core scripting concepts and let them explore the possibilities when pairing programming with engineering simulation tools.

Separately, a pilot 'lab in a box' has been created which uses PyFluent within a Jupyter Lab environment to replicate a basic, introductory fluid dynamics lab. The purpose of this tool is to enable early-years students to benefit from industry-standard simulation tools such as Ansys Fluent underpinning an 'experiment.'

When looked at in one way, these two projects have opposite goals: the first, to expose students to more complexity and the ability to expand their engineering practice through coding; the second, to reduce the complexity of a simulation tool to help early-years students use it. However they both provide insight into the power of combining scripting and simulation in different areas of undergraduate education.

2 METHODOLOGY

2.1 CodeFest Events

There is a reasonably established tradition of 'hackathon' type events being used for student teaching, team-building and awareness-raising, as well as the more commercially-focused industry hackathons that have become common [8]. As a new set of software packages, PyAnsys is an ideal tool to introduce in the focused environment of such an event. However, since there was no free choice of which software students could use, these pilot events were advertised as 'Codefests' rather than true hackathons. A 2-day event was held at Cornell University in September 2022, followed by a 1-day event at Virginia Tech university in April 2023, with two further events planned in summer 2023.

CodeFest events were planned in coordination with an academic 'champion' at the university: a professor in the engineering faculty who felt that these events would benefit their students. The planning process involved not just the event logistics, but engagement with the academic champions in the months before the event to decide which types of challenges had the most valuable learning outcomes, since research on coding events shows that understanding desired outcomes is key to students getting the most out of the events [9].

The CodeFests were advertised to students 2-4 weeks ahead of the event, through a variety of means tailored to the university ecosystem: emails from faculty admin, a slide at the end of lectures to relevant student groups, small flyers for cafeteria tables and similar. In both cases this strategy was successful and over 100 students registered for each of the events. Students who attended were asked to form teams (and encouraged to make those teams cross-disciplinary) to attempt the challenges. Prizes of reasonable value (approx. 100 U.S Dollars per person) were offered to the winning team, with smaller prizes for creative solutions and other outstanding work.

2.2 Jupyter Lab 'lab in a box'

Jupyter Notebooks have become increasingly popular in education, as they offer a collaborative working environment which can combine text, images, code, web resources and more [10]. In engineering education, they can help to present complex computations in a way that complements traditional equation-focused teaching [11]. We therefore decided to explore this environment as a way to expose students to simulation with appropriate text, images and links to improve their understanding.

The ‘lab in a box’ style Notebook was developed as a project during a hackathon event, by a small team of 4 people over 24 hours. The motivation for creating a ‘lab in a box’ came from the idea of using powerful simulation tools in place of lab experiments, especially where universities may not have the resources for physical lab equipment, or remote learners may not be able to access it. Simulation can provide a ‘real world’ experiment to compare with theory, and there can be significant learnings from the visualisation capabilities in subjects such as fluid dynamics [11]. However, introductory level students who might benefit most from such visualisations are unlikely to have been trained in industry-standard simulation software, since this is time-consuming and often treated as a ‘readiness for industry’ course option in later years.

The project, then, was to attempt a proof of concept using Ansys Fluent with the python libraries available to create an easy-to-use lab, with simple instructions and user interface, powered by Ansys Fluent underneath. This was implemented in Jupyter Lab, which provides additional flexibility to Jupyter Notebooks. In particular, the ability to ‘hide’ code cells alongside the standard markdown cells means that the code running Fluent could be hidden from students taking the lab, but editable by professors or lab assistants if they wanted to add extra aspects to it.

3 RESULTS

3.1 CodeFest Events

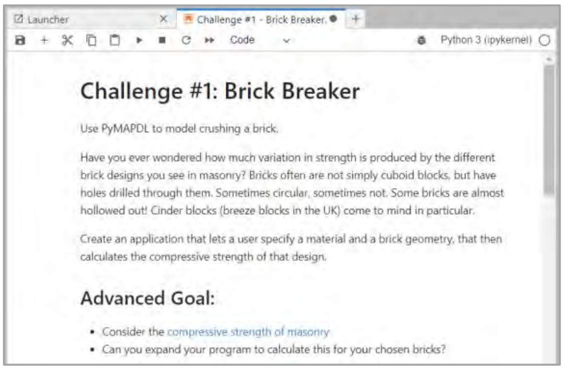
Overall, both events held to date have been judged to be a success, with positive feedback from both students attending and the professor champions.

At both events, despite targeting advertising primarily at undergraduate students, we found Masters and PhD students formed a large proportion of the attendees (34% at Cornell, 45% at Virginia Tech), showing that research students see the potential for combining scripting with simulation tools. Students attended from multiple disciplines: Mechanical Engineering, Computer Science/Computer Engineering and Aerospace Engineering dominated representation, but others from disciplines like Electrical Engineering also attended.

3.1.1 Cornell 2022 CodeFest Results

At this first event, student teams were presented with a choice between ‘guided’ challenges – essentially a set of coding exercises to work through with a small project at the end to apply their new knowledge, designed to introduce students to Python and programming – and ‘general’ challenges, which posed a problem, suggested an Ansys solver to use, and then left teams to create their own solutions using the PyAnsys libraries.

This was a 2-day event, and we saw significant drop-off in attendee numbers between the first day (a Friday) with 71 attendees and the second day (Saturday) with only 25 making it to the end of the second day. Those teams that did complete the challenges, however, produced excellent work showing they had mastered the necessary aspects of both Python and Ansys MAPDL to solve the problems we presented them with. An example of a challenge and a student team output is shown in Figures 1 and 2, showing how the students were able to engage with both UI creation through Python and controlling the MAPDL solver in the background.



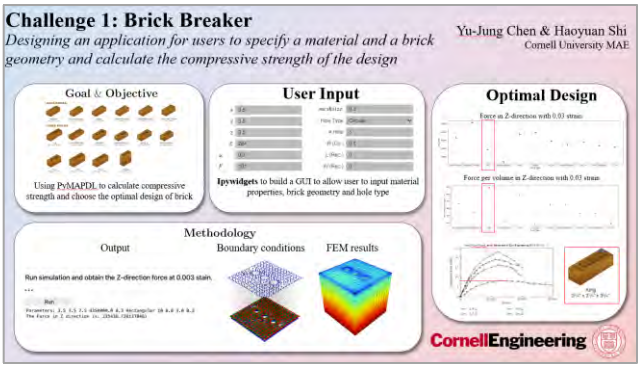


Fig. 1. 'General' challenge as presented to students

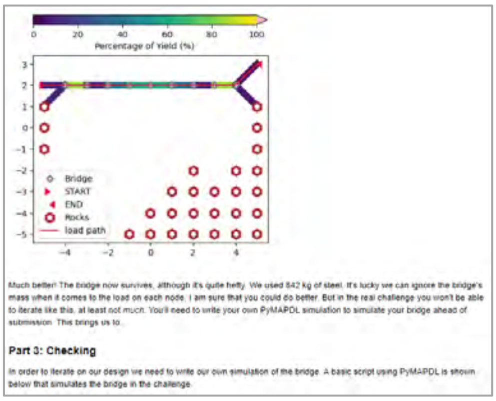
Fig. 2. Final results from one team tackling this challenge

3.1.2 Virginia Tech 2023 CodeFest Results

At the second event, we drew on learnings from the first and offered a new type of challenge which was partly guided and partly open-ended, where students were expected to use coding to find an optimal solution to a simplified 'truss bridge' type problem. This focused more on the coding challenge rather than the engineering challenge, since this was where students had struggled more at the Cornell event, but engineering understanding and validation of the team's solutions was still required for success. We also restricted the event to a single day, running from 9am to 6.30pm, and as a result saw very little drop-off in attendee numbers over the day.



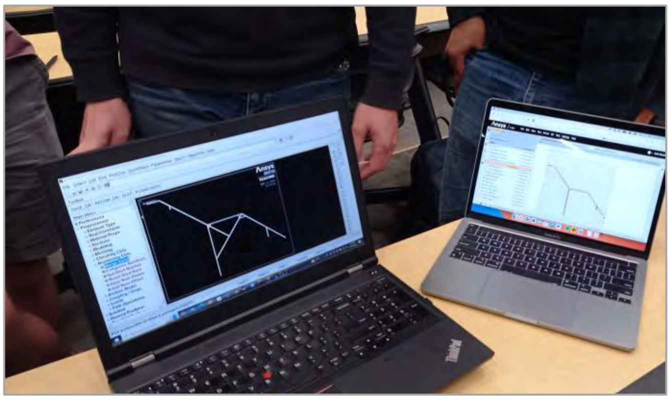


Fig. 3. Team guidance on the bridge challenge

Fig. 4. Bridge optimisation in progress on the computers of a student team

The challenge at this event was made easier to judge by the fact it was a simple optimisation problem – create a bridge across a matrix of nodes, minimise mass without yield failure. Students were encouraged to seek solutions through coding and then test these using PyMAPDL to confirm their behaviour and safety factor. We found that some students struggled to approach the optimisation problem through coding, preferring instead to sketch out potential design options on paper or whiteboards with engineering calculations done by hand. However, once students engaged with the challenge fully, they were able to harness the power of optimisation and validation. Introductory information for the challenge, and one team's bridge design in progress at the event, are shown in Figures 3 and 4.

3.1.3 Feedback, Lessons Learned and Future Plans

The students who participated in the events and were present at the end were asked for feedback, using an anonymous 'two sticky note' method: one for positive comments, one negative. At the 2-day Cornell event, there was sufficient drop-out on day 2 that this was not representative of most attendees. At the Virginia Tech event, however, this we gathered feedback from >50% of attendees, shown in Table 1.

Table 1: Anonymous feedback from VA Tech Ansys Codefest participants

'What I enjoyed'	'How could we improve?'
It was fun. Great staff.	Difficult documentation, wasn't helpful.
This was fun.	Instructions could be clearer, could be more code heavy.
Good food, not "corporate," friendly people, stickers, not too code heavy.	To me, it felt like the deadline is a bit short.
Food is good. Staff seemed sensible.	More detailed documentation would be preferable to get through details.
Impressed with the challenge. It helped me understand the application of Python in solving impossible challenges given the materials and constraints we had to work with this.	I'm not good at social coding. Love code and CAD otherwise. Not a Mechanical Engineer.
Python interface for APDL helps with automation. A good exercise to develop coding skills. Of course, I enjoyed the snacks and goodies.	More robust tutorial on problem. More focus on mechanical analysis portion such as learning about defining geometry and extracting results.
I made new friends. The problem was very interesting.	Finding documentation was a bit tough, process could be easier.
Good food, good swag, friendly staff, staff was nice and helpful.	Problem was too difficult to solve in the time given.
Food is great and great support from the staff.	Would prefer to see each group's designs at the end.
Met people, learned about how MAPDL is integrated into the backend of Ansys.	Problem is challenging for Python beginners. Need a leader of the team to do efficient work, but difficult in rapidly formed team.
Met fun teammates, creative problem solving, got more familiar with Python, had fun, and great networking.	Getting the coordinate was a big challenge, documentation was very difficult, took too much time to figure things out, didn't like the struggle signing in.
Learned a lot, met new people, great food, and great instructors.	Spend first hour explaining problem/example, Difficult for non-programmers.
Liked the format of challenges, the help, food, and the organization of event.	Tutorial on coding – many of us have never done coding.
Super helpful and friendly staff, loved the interactions.	Poor environment, simulations slow, some objectives/processes unclear.
Group work on the challenges, cool/helpful Ansys employees.	Syntax not clear, way too hard to submit answer, rubric unclear.
Team was helpful, challenge was fun to solve and fun to work with my team.	Documentation difficult to parse, incorrect values given initially, thought there would be more Ansys Mechanical, confusion on how to get there.
Format of challenges, comfortable environment, Ansys staff was helpful.	Teach more about Ansys before we start.
Good challenge, really enjoyed.	Demonstrate cases on familiar problems to make sure the programming in environment is understood before we start.
Challenge was fun and an interesting problem learning how to use APDL was more interesting than just Mechanical.	Start of program was too steep of a learning curve, felt more Python than Ansys. We were essentially blind trusting the program. If it ran, great. Need heavy programming skills to be able to push.
Engaging and fun, thanks for making me spend a laze Saturday a better way, helped me get new connections.	Wish there was more instruction on scripting, unclear instructions on actual challenge, wish there was more Ansys Mechanical integration
Whole experience was lovely. Loved to interact with new people and work together as a unit.	Wish there were more Ansys and less Python, based on fliers expecting more of a seminar, documentation needs improved.

Enjoyed how open ended the design process was. Left with a bunch of different ways to approach a problem.	Setup of challenge was frustrating, beams had to be 1 unit which is annoying, could do something more "polybridge."
Very well done overall, learned a lot about environment and scripting within it. Staff and experience was great.	
Intention is good, helpful to understand PyAnsys APIs, networking, fascinating problem and getting used to cooperation.	

Overall, the feedback shows that the social and challenge-related benefits of hackathon-types events were mostly successfully delivered, but there were challenges around coding skills level, particularly for students in engineering disciplines. Teams with computer scientists tended to do better for this reason, although teams of computer science students on their own also struggled, with engineering terminology or fundamental physical understanding. Teams combining both did best. Relatedly, another area requiring improvement, based on the feedback, is the documentation of the PyAnsys libraries, which were originally developed to support expert users of Ansys solvers (those who might already have been scripting in MAPDL, for example). For student users this documentation may need to make fewer assumptions of prior knowledge.

Our academic Champions at the universities were not asked for formal feedback, but both were positive about the events overall and interested in holding more in future. Our VA Tech champion was also interested in the potential to turn our ‘bridge-building’ challenge into a more open-ended teaching tool.

Two further CodeFest events are planned in 2023, at which the technical challenges and support required will be explored further, with one of these events focusing more on postgraduate/research students to see how this affects outcomes and feedback.

3.2 Jupyter Lab ‘Lab in a Box’ Results

The lab use case was based on an early-years fluid dynamics experimental lab run each year in the University of Oxford Engineering department, intended for students who have had lectures on potential flow theory but have not yet been exposed to real fluid flow. It consists of measuring the air pressure at points around a cylinder and showing how the measurements diverge from the predictions of potential flow theory downstream of the cylinder. This allows students to examine the assumptions of potential flow theory through exposure to real, viscous and rotational flow.

Since Fluent simulations can output pressure, they can exactly replicate this lab (minus additional learnings about physical measurement techniques), and potentially add more value through flowfield visualisations, velocity or possibly other variables.

3.2.1 Implementation Details

The Jupyter Lab exercise was thus designed to lead students through a reminder of what potential flow theory predicts, a discussion of the ‘experimental’ setup, and a slider which would allow them to explore different flow speeds spanning laminar and turbulent Reynolds numbers, all without needing them to directly interact with the standard Ansys Fluent user interface which is designed for experienced CFD users. Outputs in Jupyter Lab are in the form of the 2D velocity and pressure fields. Figures

5 and 6 show an example of the Jupyter Lab interface (including UI features such as sliders and buttons implemented using ipywidgets[12]), and the output in Ansys Fluent if it is chosen to show Fluent on screen, or in the Jupyter Lab interface.

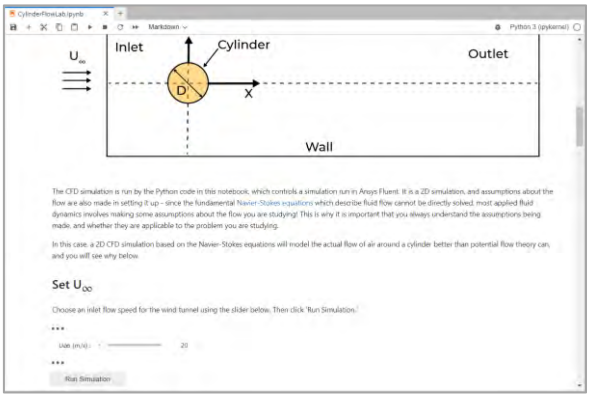

Fig. 5. Jupyter Lab interface with instructions and simple button/slider controls to set values in Fluent and run the simulation

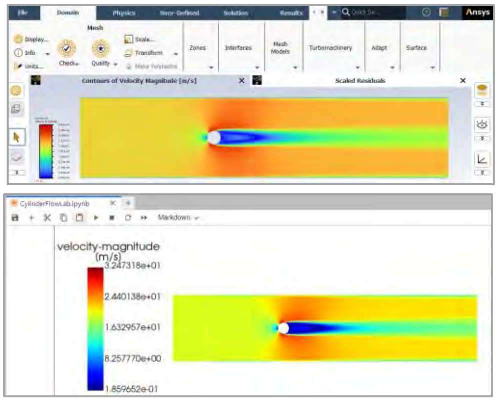

Fig. 6a) and b) Resultant velocity flowfield displayed in a) Ansys Fluent and b) Jupyter Lab, depending on GUI chosen

3.2.2 Lessons Learned and Future Plans

Overall, the proof of concept Jupyter Lab was relatively easy to create – this is something that we could envision professors or student assistants being able to make in future, and customise to their lab requirements.

We plan to share this Jupyter Lab resource in the second half of 2023 with academic users, and get feedback on the ease of use and ease of customisation. We also plan to develop similar resources for other simulation software, for example for mechanical or electronics labs, using PyMAPDL, PyAEDT or other PyAnsys toolkits.

4 SUMMARY AND ACKNOWLEDGEMENTS

In summary, we have found significant interest from students in learning how to couple scripting with simulation tools, for their own development and for their degree work, though there are some inherent challenges to overcome in introducing these through ‘hackathon’ type events, particularly around gauging students’ skills at coding ahead of the event and adapting material appropriately.

We also believe there is a significant opportunity in harnessing the power of scripting, and Python in particular, where simulation tools allow this, to deliver simulation outputs in a format which is accessible to untrained, early-years students. Based on our experience, there are potentially some easy wins in this area for simple use cases where visualisation would strongly support learning outcomes.

We would like to acknowledge the support of Professor Rajesh Bhaskaran at Cornell University and Professor Bob West at Virginia Tech University for partnering with us to deliver the CodeFest events on their campuses. We would also like to acknowledge Dr Christopher Vogel at the University of Oxford for confirming details of the fluid dynamics lab exercise which we attempted to replicate in Jupyter Lab.

ABSTRACT

Engineering for One Planet (EOP) is an initiative to transform engineering education and equip all future engineers across all disciplines with the fundamental skills and principles of social and environmental sustainability.

Catalyzed by The Lemelson Foundation and VentureWell in collaboration with hundreds of sustainability advocates across sectors, the EOP initiative envisions a world in which all engineers play a critical role in ensuring that the solutions of today do not become the problems of tomorrow, restoring and regenerating our environment, and improving lives for all.

EOP is accelerating curricular transformation by supporting faculty change efforts and fostering collaboration among stakeholders across sectors. Experts from academia, civil society and government co-developed the EOP Framework in 2020, including an adaptable and adoptable menu of core and advanced sustainability and leadership learning outcomes. Five universities pilot tested the EOP Framework in curricular changes over two years, and the EOP Framework was revised in 2022. In 2023, EOP launched companion teaching guides with step-by-step guidance and free teaching resources for integrating learning outcomes from the EOP Framework.

To date, more than 120 faculty have used the EOP Framework to generate curricular changes in dozens of diverse engineering disciplines and programs, impacting thousands of students. EOP makes its teaching tools available for free and is designed for flexible adoption and adaptation to encourage rapid expansion of sustainability into engineering education.

This presentation will enable participants to learn about the resources available through EOP, gain ideas from successful curricular change approaches and get involved in EOP’s growing global community.

1 INTRODUCTION

1.1 Rationale

Sustainability has been identified across all sectors, from government to industry to academia, as a top priority, especially as it relates to developing leading edge solutions to national and global challenges (e.g. climate change), protecting nature and the environment, ensuring environmental justice, and advancing human health, welfare and prosperity. Large industrial firms from across the globe are prioritizing sustainability and recognizing its importance to future national competitiveness and growth, leading to gaps between the demand for green skills and the supply of talent [1]. A recent study with nearly 7000 student respondents from around the world found that 90% of students were concerned about the effects of climate change, and felt that sustainable development should be universally taught in higher education yet only 26% of respondents felt their coursework was covering these issues in depth [2]. The environmental challenges we face are increasingly complex and severe, and disproportionately impact historically marginalized and low-income communities due to longstanding systemic injustice and discrimination. The demand for STEM graduates and green skills are both rapidly increasing, requiring an escalation of sustainability-infused STEM education.

Successfully addressing global challenges requires fundamental and systemic change in how we define the role of engineering and engineers, collectively prepare the 21st century workforce, and develop cutting-edge technological solutions that are not only more sustainable but net zero and even regenerative. It also requires fundamental and systemic change in who will want to become an engineer, graduate as a trained engineer, and pursue a career as a professional engineer. It is imperative that people from communities that bear the brunt of the negative impacts of climate change and environmental degradation are able and encouraged to share their perspectives, knowledge, and lived experiences as engineering leaders and problem-solvers [3],[4].

Engineering education operates within a complex system of interdependent stakeholders and policies, all of which exert forces on education but do not work in unison. Among these stakeholders are professional engineers, engineering employers, professional engineering societies, engineering education accreditation bodies, government regulators and consumers. Efforts to change engineering education, such as the Engineering for One Planet initiative, must acknowledge, account for, understand, and engage the interests of diverse stakeholders and foster collaboration.

1.2 Background

Beginning with research efforts in 2017, the Engineering for One Planet (EOP) initiative was officially launched in 2020. EOP is a coalition of hundreds of organizations and individuals seeking to transform engineering education to prepare all future engineers with the sustainability and related professional skills and knowledge that are increasingly required in engineering professions. Catalyzed by The Lemelson Foundation and VentureWell —two US-based non-profits created by the late Jerry Lemelson who was a prolific US inventor with over 600 US patents—the EOP initiative aims to engage stakeholders to infuse fundamental environmental and social sustainability topics across academic engineering curricula, programs, departments, and institutions.

With input from hundreds of experts in academic, industry and civil society, the EOP initiative has published the EOP Framework [5], a menu of student learning outcomes that all graduating engineers should acquire to ensure they are equipped to protect and improve our planet and our lives. Designed to be widely adaptable, the EOP Framework is mapped to ABET accreditation requirements [6], the United Nations Sustainable Development Goals (UN SDGs) [7], Bloom's Taxonomy [8], and simplifies the task of infusing sustainability and related professional skills into a broad range of engineering courses and programs. The EOP Framework serves as a platform for curricular change and has become a cornerstone of the EOP initiative.

2 METHODOLOGY

The EOP initiative has been developed and is evolving through collaboration among hundreds of sustainability advocates across sectors —from academia, industry, nonprofits, governmental agencies, accrediting bodies— geographies, and lived experiences. EOP seeks to ensure all future engineers across all disciplines learn the fundamental skills and principles of social and environmental sustainability. The results of a thematic assessment through in-person interviews and conversations with engineering practitioners and educators [9], [10] and the results of the EOP Literature Review Report [11] demonstrate the need for a sustainability implementation tool such as the EOP Framework as follows: engineers play a critical role in creating a healthy, flourishing world, and their work has outsized impacts on our world. Engineers must possess sustainable mindsets, skill sets, and professional preparation. This is necessary because the industry demands it and to ensure that the engineering solutions of today do not become the problems of tomorrow. However, many of today's graduating engineers are not learning sustainability-focused concepts, tools, and methodologies through their engineering educational training. Therefore, there is a need to intentionally incorporate these concepts into engineering education.

Numerous activities have taken place since the launch of the EOP initiative in 2020. Today, the EOP initiative utilizes three interrelated strategies to transform engineering education and ensure all engineers are equipped to design, build, and create in environmentally and socially sustainable ways: 1) EOP Teaching Resources: to facilitate curricular change, assessment, and peer learning (e.g., EOP Framework [5] and two companion teaching guides; Quickstart Activity Guide [12] and Comprehensive Guide to Teaching Core Learning Outcomes [13]) 2) Catalytic Grants: to foster curricular change through funding and mentorship (e.g., EOP Pilot Grant Program (PGP) and the American Society for Engineering Education (ASEE) EOP Mini-Grant Program (MGP), and 3) Collaborative Community: to support collective action across sectors to accelerate change (e.g., EOP Network).

2.1 Strategic Action 1: EOP Teaching Resources

The EOP Framework: Essential learning outcomes for engineering education (Fig. 1), first launched in 2020 and revised in 2022, is a cornerstone of the EOP initiative, the first of its kind to guide coursework, teaching tools, and student experiences that define what it means to be an engineer who is equipped to protect and improve our planet and our lives [5]. The EOP Framework is not a research framework but a practical implementation tool that supports educators in integrating environmental and social sustainability concepts and tools into engineering courses, programs, and departments. It provides faculty with a vetted menu of student learning outcomes that every graduating engineer, regardless of subdiscipline, needs to acquire to design, code, build, and implement solutions that are socially and environmentally sustainable.

Fig. 1. *Engineering for One Planet Framework Graphic [12]. Adapted from EOP Framework.*

The EOP Framework fills a gap in curricular development by detailing core environmental and social sustainability learning outcomes, as well as related leadership skills, that would enable all engineering graduates to be prepared to protect and improve our planet and our lives. It was co-created by a community of hundreds of experts from a range of identities, lived experiences, geographies, and sectors, including academia, industry, nonprofit, government, and philanthropy.

The EOP Framework comprises nine topic areas: Systems Thinking, Environmental Literacy, Responsible Business and Economy, Social Responsibility, Environmental Impact Assessment, Materials Selection, Design, Critical Thinking, Communication and Teamwork. Each topic area has a list of core and advanced student learning outcomes that are measurable and mapped to ABET's engineering accreditation requirements which are delineated through seven student outcomes in Criterion 3, which include sustainability competencies [6], as well as to the UN SDGs [7] and Bloom's Taxonomy [8].

Additionally, to better support faculty efforts to integrate the EOP Framework and sustainability-focused content into engineering courses and programs, two companion teaching guides were launched in 2023. The Quickstart Activity Guide outlines step-by-step and timed learning activities for one core learning outcome from each of the nine topic areas [12]. The Comprehensive Guide to Teaching Core Learning Outcomes provides learning activities to achieve each of the 46 core learning outcomes over the nine topic areas of the EOP Framework [13]. Both teaching guides and the EOP Framework are available for online and for free at www.engineeringforoneplanet.org.

2.2 Strategic Action 2: Catalytic Grants

Lemelson has funded three EOP grant programs, driving curricular changes and generating teaching tools, assessment tools and insights to help other faculty and institutions with similar efforts: 1) The EOP Pilot Grant Program (PGP) and 2) The American Society of Engineering Education (ASEE) EOP Mini-Grant Program (MGP), described below, and the 3) EOP Institutionalization Grant Program.

The PGP was designed to test the EOP Framework between 2020-2022. The program awarded seed grants to five US-based institutions (up to $40,000 each supported by community of practice meetings) to test the integration of learning outcomes from the EOP Framework in diverse curricular offerings.

Funded by Lemelson and launched in 2022, the MGP's first cohort awarded seed funding ($8,000 and mentorship) to 13 US-based schools, five of which are Minority Serving Institutions (MSIs) [14]. In 2023, the EOP MGP awarded 14 grants and is expected to award grants to approximately 12 additional schools in 2024.

Lemelson has also funded larger "institutionalization" grants to expand integration of sustainability at a number of higher education institutions and is engaging other funders to support EOP-related curricular changes.

2.3 Strategic Action 3: Collaborative Community

Due to the complex nature of the engineering education system, stakeholders identified the need for sustained collaboration to drive top-down and bottom-up approaches to transforming engineering education. The creation of the EOP Network in 2021 was a response to this need. This impact network seeks to foster collaborative actions among its membership of students, faculty members, higher education leaders, as well as industry, nonprofit, and government professionals. The network is voluntary, non-hierarchical, and self-governed, and it is supported by a paid network manager who facilitates member collaboration and project teams, plans and delivers events, and ensures the network operates effectively.

Other examples of collaboration through the EOP initiative include: the 2022 EOP Scaling for Impact Workshop supported by the National Science Foundation (NSF), and the development of an open-sourced Sustainability Toolkit to support United Kingdom-based educators in integrating sustainability into engineering education. A steering group including EOP representation and led by the UK's Engineering Professors Council (EPC) is co-creating the Sustainability Toolkit, which is funded by Siemens and the Royal Academy of Engineering.

3 Results

3.1 EOP Teaching Resources

Since its launch in 2020, the EOP Framework has been shared with thousands of academic and industry professionals in the US and around the world through presentations, reports, articles, and grantee activities. Examples of conferences in which EOP was shared include the ABET Annual Symposium, ASEE Engineering Deans Institute, ASEE Annual Conference, Annual Colloquium on International

Engineering Education (ACIEE), International Symposium on Sustainable Systems and Technology, and several other academic conferences.

Through the PGP, five diverse US universities pilot tested the EOP Framework in curricular changes that reached nearly 6000 students. In 2022, the EOP Framework was revised to incorporate feedback from pilot grantees and other stakeholders during an open commenting period. Over 600 comments were resolved that led to key modifications to the EOP Framework, including: defining and emphasizing sustainability as both social and environmental, revising outcomes to be measurable and tracked to Bloom's Taxonomy, aligning the EOP Framework learning outcomes to specific ABET student outcomes, and making a stronger connection to Diversity, Equity, Inclusion and Justice (DEIJ). The feedback also led to the development of two new EOP Framework companion teaching guides.

The EOP Framework has also been used to advance sustainability efforts internationally. Two examples include: use as a framing device where EOP learning outcomes were mapped to all courses in a new sustainable systems in engineering transdisciplinary degree program at the University of Calgary, and as a key resource to guide the development of the aforementioned Sustainability Toolkit for engineering education in the UK.

3.2 Catalytic Grants

As previously noted, the two-year PGP enabled five universities to pilot test the EOP Framework in curricular changes. PGP awardees found significant value in the EOP Framework and shared several key findings that can assist others seeking to make similar changes. In total, grantees integrated learning outcomes from the EOP Framework to develop or modify a total of 61 courses. Of these, 50 were required engineering courses, far exceeding the minimum goal of one course per institution, and impacting nearly 6,000 students in only 2 years [15].

The first cohort of the MGP concluded in January 2023 with an online, public symposium featuring poster presentations by all participating schools about their efforts and impact during the program. In total, awardees used sustainability-focused learning outcomes from the EOP Framework to develop or modify over 30 courses, reach over 1600 students, and train more than 30 faculty in less than a year.

3.3 Collaborative Community

In 2022, there was an open application period to join the EOP Network with a focus on intentionally broadening the participation of applicants from groups traditionally marginalized in engineering, including women and people of colour. A review committee selected 32 new members to join the EOP Network, expanding the network from 40 to 72 members. There is significant national and international demand to join the EOP Network. EOP Network members convened in person for the first time in October 2022 on the Boeing campus in Seattle, Washington. Participants formed team projects to pursue a variety of projects, including: developing a conference toolkit to support EOP outreach efforts, a guide to prepare students for sustainability-focused industry interviews, establishing an industry internship, conducting a funder landscape analysis, and establishing an EOP evaluation plan with key performance indicators.

The NSF-funded EOP Scaling for Impact Workshop engaged 100 stakeholders from various sectors and backgrounds to collaboratively identify approaches for taking the EOP initiative to scale. A report will be publicly disseminated in 2023.

4 Summary and Acknowledgments

4.1 Summary

Environmental and social sustainability have been identified across all sectors, from government to industry to academia, as critical for the health of our planet and lives. Through the vast reach and scope of engineering activities, engineers have the potential to positively address social and environmental challenges and/or to inadvertently contribute to future problems. To protect and improve our planet and our lives, all engineers must be prepared with fundamental skills in sustainability. Currently, most engineering graduates have limited exposure to sustainability in higher education. Transforming the engineering education system is complex and requires the collaboration of people and organizations across sectors including academia, industry, accreditation bodies, as well as the communities disproportionately impacted. The EOP initiative's vision is that sustainability will be a core tenet of the profession. To achieve this vision, sustainability must be infused throughout engineering education. Since its official launch in 2020 with support from The Lemelson Foundation, the EOP initiative has evolved and made significant strides to enable stakeholders to co-create the initiative's core tools and strategic roadmap and to spur curricular changes that have reached thousands of students. Together, the growing, international EOP community is helping drive curricular changes to infuse sustainability into engineering education and the engineering profession to ensure that all engineers are prepared to address today's challenges while seeking to maximize the positive and avoid the potential negative impacts in the future.

4.2 Acknowledgements

The authors would like to acknowledge and thank the contributions of the hundreds of stakeholders that have provided feedback, ideas, and their valuable time to advise the EOP strategy, co-create the EOP Framework, inform the development of the two EOP Framework companion teaching guides, collaborate in the EOP Network and contribute to numerous other events and activities over the years. The authors would also like to acknowledge and thank The Lemelson Foundation, VentureWell, Alula Consulting, the National Science Foundation, the Kern Family Foundation and Boeing for their roles supporting these efforts.

ABSTRACT

SISSTEM "Sustainable Island Solutions through Science, Technology, Engineering and Mathematics" is a higher educational programme created in 2019 at the University of Aruba in response to the need for engineering education and research in Small Island Developing States (SIDS). In this contribution, the SISSTEM programme is introduced, and how SISSTEM equips engineering students with hard and soft skills while addressing local sustainability challenges is showcased through two case studies.

The first case study presents a bachelor course that combines sustainability theory with a teamwork project in which students conduct an energy audit to a local institution. With this course, students acquire skills to support the energy transition in Aruba. The second case study focuses on the involvement of university students in the creation of a citizen science mobile phone app to tackle waste challenges. This case study presents how students can become agents of change to contribute solving waste management challenges on the island.

Overall, these two case studies showcase how by combining theory and project-based education, students learn to integrate STEM knowledge into multidisciplinary solutions to complex sustainability challenges. In fact, given the cross-cutting nature of sustainability transitions, educating students in integrating the natural environment, technical, social, and economic aspects in engineering solutions is key to increase resilience of islands. As such, at SISSTEM, students acquire hard skills related to their engineering specialisation, as well as soft skills such as integration of disciplines, contextualization, and collaboration.

1 INTRODUCTION

1.1 Small Island Developing States

Small Island Developing States (SIDS) share sustainable development challenges given their remoteness, relatively small size, and fragile environments (Briguglio 1995). In addition, SIDS' vulnerability to external shocks is exacerbated by climate change (de Águeda Corneloup and Mol 2014), making sustainable development imperative to increase resilience in SIDS.

Technological innovation is key for sustainable development and in this regard, engineering education that integrates technology knowledge with principles of sustainable development is essential (Kamp 2006). While engineering education plays a fundamental role for sustainable development, STEM (Science, Technology, Engineering and Mathematics) education opportunities are not always available on SIDS. In this contribution, the higher education STEM programme named SISSTEM (Sustainable Island Solutions through STEM) at the University of Aruba is presented.

1.2 STEM programme at the University of Aruba.

Aruba is a Southern Caribbean island of 180 km² (Derix 2016) with a population of about 112,000 inhabitants (Central Bureau of Statistics Aruba 2020). Until 2019, engineering education was not available on the island, leading to talent drain and creating a dependency on external expertise (Mertens et al. 2023). In response to this need for engineering education and research, the programme SISSTEM was created at the University of Aruba through a collaboration with KU Leuven and with funding from the European Union (Mertens et al. 2022).

SISSTEM consists of a bachelor programme that offers three specialisations (Bio-environmental science; Information and Data Science; Technology and Engineering), a master programme, and 10 PhD research projects (University of Aruba 2023). The principles of education for sustainable development are applied, providing students with state of the art knowledge and equipping them with key skills to solve sustainability challenges (Mertens et al. 2023). In practise, educational material provided by KU Leuven professors is adapted to the SIDS context by academics at the University of Aruba (Mertens et al. 2022), fomenting the local application of STEM knowledge through field trips, practical assignments and educational projects. How local challenges are targeted through education and research is shown through two case studies elaborated in the sections below.

2 TARGETING LOCAL SUSTAINABILITY CHALLENGES THROUGH EDUCATION AND RESEARCH:

2.1 Case study A: Learning while promoting energy efficiency at local institutions.

The SISSTEM bachelor curriculum (University of Aruba 2023) includes the course "Integrative Project" in the 1st academic year with the purpose of teaching the integration of diverse disciplines on sustainability solutions. In this course, students conduct an energy audit of the building of a local institution, with the final goal of providing sustainability advice. Hosting parties have been the Dutch Marine base located in Aruba, the Queen Beatrix International Airport of Aruba and a local hotel named Amsterdam Manor. During the current academic year, the students are conducting the energy audit at the campus of the University of Aruba, and results are expected to be incorporated into the university's long-term sustainability plans.

"Integrative Project" is a six-month course that combines theory with practical assignments. During the theoretical module, students conduct a literature review on retrofitting techniques, a process during which they are motivated to think critically on the role of contextual factors when retrofitting buildings. Then, the students conduct field work in groups of 3 to 4 students. This consists of four site visits to the hosting institution which acts as a "client". During the first session, the students learn from the "client" the experienced operational challenges and how they expect the students' work to contribute to their sustainability plans. Based on the client's request, the students elaborate a measurement plan for collecting technical data during the second site visit. This includes observations and the use of instruments such as a thermal camera for detecting energy leaks, a lux-meter for identifying the potential use of natural light, and an air quality meter (Figure 1). Additional data required such as energy bills are requested by the students to the institution. During the third site visit, semi-structured interviews with employees from different departments are conducted. This interaction with the energy users is key for students to realise the role of social adoption when implementing technological developments. Based on the collected technical, social, and economic data, students provide to the "client" short- and long-term recommendations for energy efficiency. The results and recommendations are shared through an oral presentation and a written report delivered to the "client" on the fourth site visit (Figure 2).

Figure 1: Student collecting data with a thermal camera during field work.

Figure 2: Students presenting the results and sustainability recommendation to the "client".

Learning outcomes:

The learning outcomes are measured by assessing individual and group assignments. In addition, after course finalisation, students are asked to reflect on the learning experience (University of Aruba 2020).

With this course, students acquire skills to support the energy transition in Aruba. Learning to apply sustainability strategies at local companies has been defined by students as an eye opener – *“This course was something new, working with a client that has a set of requirements was something I have never done. Learning about data presentations, and how to write a proper assessment report was really eye opening.*”

In addition, the collaboration skills obtained by working with peers were also highlighted – *“During the integrative project I have learned to work better in the group and come to terms with compromises. I have also learned that in Aruba there are people/businesses interested in Sustainable Development”.*

Overall, this course has proven to equip students with skills necessary for sustainable development – *“I have acquired new skills, I have improved my management skills, acquired knowledge on policy making and learn about recommending”; “I have learned how to work better in a group and how to work in a professional way with organisations. I have also learned how to identify sustainability problems that are not obvious”.*

This case study presents how sustainability can be taught as a tangible concept by the inclusion of practical experiences in addition to theoretical lectures. As a lecturer, it is interesting to yearly evaluate and adapt the course content depending on the hosting institution. Other changes are made based on the skill needs by the cohort of students. For example, initially the course only included teamwork assignments, and later, it was decided to include individual assignments as well, for students to develop skills and knowledge both as individuals and as team members.

2.2 Case study B: Involving students in developing a citizen science mobile phone app to tackle waste challenges.

This case study presents the involvement of students in developing a locally applicable citizen science mobile phone app to track post-consumer waste. This was developed by applying a citizen science approach, which increases students’ engagement through active and research-based learning (Mitchell et al. 2017).

This project has been executed within the scope of the collaboration between the University of Aruba and KU Leuven which allows for international student exchange both ways. In this case, two software engineering students from KU Leuven showed interest in conducting together their master thesis on building the above-mentioned mobile phone application. While the app development task was assigned to the master students, a multidisciplinary team contributed to the design, including academics from KU Leuven and the University of Aruba. Input from independent software engineers and stakeholders in the field of waste management and citizen science was collected through brainstorming sessions. The app has been developed and tested at the campus of the University of Aruba, providing the opportunity to learn not only for the students developing the app but also for those students testing and evaluating the product.

The research conducted for the app development consisted of a desk research phase followed by an app development and testing phase. First, the students elaborated the research proposal. For that, the students conducted desk research to gain knowledge on the state of the art of citizen science mobile phone apps and on other fields key for developing this specific technology, such as plastic waste and SIDS' characteristics. In addition, brainstorming sessions involving students and academics, both from KU Leuven and from the University of Aruba, facilitated knowledge transfer across different educational levels and the integration of different points of view.

Next, the two KU Leuven master students conducted an international research stay of two months at the University of Aruba with the goal of developing and testing the app. First, the students focused on understanding the context, this included visiting a local plastic recycling centre which also acts as a collection centre for other waste fractions. In addition, the students sorted the waste disposed at the recyclable bins at the campus, identifying the most consumed products. Additional knowledge on the local applicability of the research was acquired through discussion sessions with expert software developers and an Aruban stakeholder in the field of plastic waste and citizen science.

The app was developed following an agile method. After four weeks, the first prototype was ready to be tested. The test was conducted by university students from different backgrounds during a workshop. A total of three workshops were organised, consisting of a brief introduction to waste followed by 20 minutes during which the students tested the app. Students were assigned random waste items representing the most common disposed products, and were asked to record data on the assigned waste items by using the app. The impressions on the usability and user-friendliness of the app were collected through a questionnaire completed by all workshop participants, a total of 46. While the user friendliness of the app was rated "very easy (to use)" by 69.6% of the participants and "easy" by the remaining 30.4%, the users recommended including additional descriptive features. For example, extra pictures and explanatory text to facilitate waste items classification, especially for the category "other non-recyclables". Of all the respondents, 82.6% agree that the app would help them sort the waste correctly. The motivational factors to use the app were ranked as follows: contributing collecting data (58.7%), reducing university's carbon footprint (45.7%), learning about recycling (39.1%) and getting rewarded for the contribution (15.2%). In addition, 78% of the participants showed interest in creating a log-in profile to follow personal waste recycling patterns. Another recommendation was to add in the app a language selection feature to choose from English, Dutch, Papiamento, and Spanish, the most widely spoken languages in Aruba. This was described as a key aspect for a successful local implementation.

After the testing phase, the thesis students worked on finalising the app (Figure 3). In this round, the students were able to incorporate their own ideas, as well as those provided by users from different backgrounds, providing an opportunity to make the creation process more multidisciplinary. The students concluded their assignment by disseminating the research outcomes to different audiences. This was done by the elaboration of a scientific master thesis manuscript and by the creation of short tutorial videos on how to use the app (Figure 4).

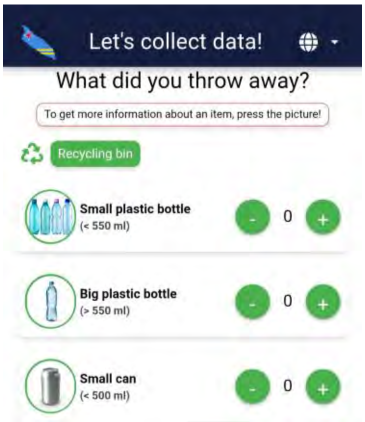

Figure 3: Screenshot from a section of the front-end of the developed app.

Figure 4: Screenshot from the video tutorial.

Learning outcomes:

The learning outcomes were measured by assessing students' skills such as autonomy, team spirit, communication, and critical thinking proven during the process, as well as the scientific rigour in the elaborated scientific manuscript and the oral defence of it. In addition, a semi-structured interview was conducted to students asking them to reflect and elaborate on their acquired skills and competences.

Students conducting an international research stay acknowledged that this experience helped them understand the contextual differences between their home country and Aruba. Technical knowledge on recycling was acquired through the site visit to the Aruban plastic recycling organisation, and a cultural understanding was obtained through interaction with students from the University of Aruba involved in the app testing. "*For cultural standpoint, it is interesting to see how people across the world think about certain issue, and here [Aruba] this is [waste] a really important issue so they really want to contribute"*.

The experiential learning approach applied in this case study, resulted in students learning to work independently. "*We learn from scratch how to do something, how to teach ourselves to do it*". Students believe this learning is an asset for becoming entrepreneurs "*We will work for our own, so for every problem, we will need to search for solutions, our own methods to face those problems*". In addition, the students believed that the setting of this project allowed them to develop a pro-active attitude "*We have to make something, but how we make it was up to us. So, we had the ability to learn things that we were interested in".* When interviewed on their acquired competences, the students highlighted hard skills, such as programming and learning about the architecture of a mobile phone application. Still, according to the students, the biggest learning is on project management, acquired by collaborating with different people. How this multidisciplinary project taught them to communicate with people from different backgrounds was identified as a valuable soft skill: *"For me it is very important for the future to have technical knowledge but to explain this to someone with less technical knowledge in this area, so still in a comprehensive way. I think it is a very important skill".*

The involvement of students from University of Aruba during the development phase supported local students becoming agents of change by participating in creating sustainability solutions. While workshops' participants were not interviewed, from the answers to the survey and open conversations during the workshops, a high interest in this project was perceived. The KU Leuven students giving the workshop quoted "*What I found really nice is that I really sensed that people wanted to change something in Aruba, and they were really motivated to use the app and give feedback to us".* In line with that, the value of making a contextually suitable mobile phone application that could support sustainable development was recognised*: "When we presented the app to them* [the students from University of Aruba]*, they gave a lot of ideas and solutions on how to make it more engaging for people in Aruba specifically. They were also thinking on how this could be good for having a better environment".*

Besides the students' learnings, this case study presents two additional major outcomes. First, it constitutes an example of how sustainability challenges can be targeted through citizen science at higher education institutions, bringing together students and academics from different disciplines. The presented approach can be replicated in future research projects to support sustainability transitions in SIDS, encouraging incorporating inputs from different faculties in the co-creation of locally applicable solutions. Next, the created app is expected to contribute to data collection which could provide insights into institutional waste production (when applied at the University campus) and national waste production (when used at household level). The app could potentially be applicable in other SIDS, constituting a tool for supporting sustainable waste management practices in the region.

3 CONCLUSIONS AND ACKNOWLEDGMENTS

In this contribution, two case studies have shown how education and research considering the specific characteristics of SIDS and the cross-cutting nature of sustainability transitions is applied through the SISSTEM programme. These case studies are not developed in isolation but are linked to SISSTEM bachelor and master theses, and to project-based bachelor courses. In this form, SISSTEM educates students in integrating the natural environment, technical, social, and economic aspects in engineering solutions. In addition to achieving academic goals, these case studies have led to initiatives that make the island more resilient. The Integrative Project course has resulted in numerous partnerships between institutions and the university, facilitating the creation of a locally applicable knowledge network. It has also supported institutions in their energy transition, which creates local examples on how to reduce dependency on fossil fuels. Creating the app tailor-made for the Aruban context provided the possibility of including user's needs and interests, resulting on a locally applicable tool to engage citizens in waste data collection.

The work conducted by students in the described projects is highly appreciated. This research was funded by the European Union (FED/2019/406-549). Its contents are the sole responsibility of KU Leuven and the University of Aruba and do not necessarily reflect the views of the European Union.

ABSTRACT

Engineering projects are frequently experienced through the complexity of knowledge co-production between experts and local communities. This involves an ability to work critically and creatively within unfamiliar epistemologies, drawing from quantitative, social and scientific methods to realise high-impact solutions. In this work-in-progress paper, we put forward a prototype for a case-control study aiming to evaluate student buy-in and learning outcomes for a cross-cultural implementation of critical mathematics approaches contextualised by sustainability challenges. We outline and discuss aspects of mathematical modelling activities that can scaffold an environment where human subjectivity amplifies the quality and relevance of quantitative arguments. As proof-of-concept, we analyse exemplary work of first-year engineering students as they design, implement, and evaluate a model of population dynamics towards proposing solutions for the endangerment of a wild species. We then identify critical learning outcomes springing from the social and subjective context that envelops the processes of mathematical modelling, analysis and communication in the real world. Our initial results show that interdisciplinary sustainability-driven mathematics activities have the potential to empower students to adopt a conscious approach to societal and environmental challenges.

1 INTRODUCTION

1.1 Knowledge Co-Production and the Connected Curriculum

Modern sustainability challenges are reportedly more effectively addressed when knowledge is co-produced between 'experts' and local communities. Research shows that high-impact engineering interventions are distinct for being context-aware, inclusive, goal-oriented, and interactive [1]. Knowledge co-production is built on the principle that the people affected by a certain project are the most suitable to evaluate its value and validity and sees non-experts as partners to judge the impact of an intervention. In practice, this involves modes of work that incorporate several ways of knowing in decision-making, planning and design. Given the fundamental character of mathematics within engineering, this paper aims at exploring the opportunities for knowledge co-production in the teaching and learning of engineering mathematics.

The challenges of uncertainty in engineering projects highlight a need for engineering education that enables students to navigate through unfamiliar epistemologies, drawing from a blend of scientific and social forms of knowledge to solve problems that can be transparently evaluated and continuously improved upon. Towards this end, the connected curriculum framework brings the idea that teaching can join different threads that had previously been considered to be unrelated, embodying public engagement as well as intellectual and ethical positions in education [2]. The aim of this connectivity is to embed an element of human complexity within day-to-day instruction, connecting the classroom to the wider world and communities around it. Similar ideas also underpin the provision of problem/project-based learning (PBL), where students learn through collaborative, self-motivated research and enquiry in solving authentic, open-ended problems. [3].

1.2 Sustainability and Critical Mathematics

Over the last three decades, a convincing argument has been made for mathematics education that is student- and community centred. Critical theorists [4,5] maintain that mathematics can be used in subjective ways to propose, sustain, or change ideas about society, economy or the environment. These pedagogies present mathematics as a creative process towards changing precarious realities, aiming to engage students in acting effectively against global challenges and to communicate quantitative ideas in an inclusive way. It is hence necessary to enable students to discover the transformative possibilities of learning mathematics to build a more sustainable world. This idea was first implemented in mathematics education for the empowerment of marginalized communities [4, 5], and has been more recently applied to present numerical evidence for arguments relating generally to real life problems [6-7].

Mathematics plays a hybrid, scientific and social role in engineering projects. Statistical mathematics and modelling can be used as a tool to systematically characterise, optimise, forecast or explain phenomena. Mathematics also plays a social role because it increases the potential of people to influence systems, processes or policies that bear direct impact on their life [5-7]. In this paper, we describe our initial efforts and experiences in designing and delivering activities that give students opportunities to reflect on how we can act more effectively via mathematical modelling.

1.3 Research questions

The rationale for the present approach to mathematics activities lies in that mathematical modelling can help students crystallise subjective ideas into “quantitative landmarks” upon which a shared understanding of a complex situation can be built [6]. This is a move away from mathematics education that is exclusively based on factual recall and routine procedures, instead opening up space for mathematics learning to be a dialectic exercise [5]. In this paper, we present mathematical modelling as a creative process, where mathematics can be communicated, evaluated, negotiated and transformed around the uncertain and non-ideal constraints of a real-life challenge. Therefore, the broad questions for this are:

- How can critical approaches to engineering education encourage students to communicate their ideas in the form of mathematics?
  - And more specifically, what are the synergies between a critical approach to sustainability education and the technical or abstract concepts in the mathematics curriculum?
- What are the lessons learnt across borders from exploring student awareness and empowerment in sustainability challenges via mathematics?
  - And more specifically, what are the features of student collaboration and exchange in sustainability-oriented engineering projects?

2 METHODOLOGY

2.1 Hypothesis-generating data

The hypothesis-generating data that motivates this study was sourced from summative student activities undertaken during the 2021-2022 academic year at a cross-disciplinary first-year engineering mathematics module. This module introduces students to engineering mathematics via collaborative case-studies exemplifying applications of mathematical concepts in science, healthcare, technology, and sustainability. For example, students are introduced to differential calculus by engaging with activities framed around the optimisation of family-run agriculture in the Global South and learn integrals by modelling non-invasive surgery protocols [8]. The course is delivered in a hybrid format, where passive activities such as knowledge acquisition are done online in preparation for staff-led workshops that activate student learning through hands-on mathematical modelling of engineering problems.

2.2 Activity Design

The source activity explored herein was themed around the endangerment of wild animals in Sub-Saharan Africa, through mathematical modelling of a finite-difference system predicting the evolution of subpopulations of pup (0 – 1 year), yearling (1 – 2 years) and adult (>2 years) animals [9]. In the activity brief, students were asked to propose solutions towards three important challenges for the survival of the species: (i) shrinking natural habitats, (ii) lethal diseases, and (iii) being hunted by local farmers. Final solutions to this activity were required to contain two discursive elements that should be based on the models and results obtained by students after performing numerical simulations. For this, students were encouraged to test their hypotheses via simulation-based cause-effect comparisons. This activity design intended to prompt students to make connections between mathematics parameters and empirical measurements, as well as mathematics-based action and their practical impact.

The activity design guided students through documenting factual mathematics knowledge such as assembling matrices and vectors, performing matrix-vector and matrix-matrix multiplication, or inverting a matrix. The main activity discussion regarded describing and comparing the effects of different survival probabilities on the total number of animals. The scaffold outlined below guided students as they chose on which subpopulation their proposed solutions should focus. These objective steps served as "quantitative" landmarks where students could validate their mathematical work against previously established criteria.

- The first landmark consisted of modelling empirical timeseries data of a wild species population as vectors that change with respect to time. This allows for assembling and solving linear systems of equations toward calculating survival probabilities of the three subpopulations of wild dogs [9].
- The second quantitative landmark was based on applying matrix multiplication toward deriving a forward/backward predictive model for each of the subpopulations of the species. This task relied on students using induction to assemble a forward system of difference equations with yearly time-steps. For backwards modelling, students need to employ the properties of matrix inversion towards predicting past populations.
- After obtaining a mathematical model that is based on matrix multiplication, inversion, and matrix-vector operations, students were asked to implement computer code to perform a sensitivity analysis towards demonstrating the effects of the survival and reproduction probabilities on the total number of living animals of the species.

2.3 Identifying examples of critical thinking in student solutions

Although students were asked to use mathematics towards determining *what* is objectively important in this challenge, such as the survival of wild animals, they were also prompted to discuss *how* this could be done in sustainable, systemic or humanizing ways. As an additional step, students were asked to give examples of realistic and feasible interventions that could result in the preservation or repopulation of the species. This activity component was included intending to steer students away from impersonal engagement with mathematics in favour of a reflection on the impact of mathematics-based creativity and action in the real world [4,5]. Based on existing frameworks for the identification of critical consciousness and mathematical critical thinking [6-7], we discuss three examples of critical thinking in student work:

- Recognising underlying assumptions in modelling and disclosing the possible limitations brought to results, contrasting and comparing different scenarios and evaluating their appropriacy as a mathematical solution (Examples 1 and 2).
- Communicating mathematical information in verbal or graphical form and vice-versa, explaining mathematical relationships and proposing analogies with real-life processes or systems (Example 2).
- Proposing sustainable and humanising solutions that are based on quantitative information obtained via mathematical modelling and that consider diverse value- and belief systems (Examples 3, and 5).

3 ANALYSIS OF STUDENT DISCOURSE

The exemplary evidence presented below was extracted from student work conducted as part of a previous study in the activity described in section 2.2 and is reproduced herein with the consent of the authoring students. These solutions were not evaluated based on their real-life feasibility, but rather on whether their underlying discourse was synthesised by a blend ethical and sustainable principles to objective mathematics reasoning. The content of student proposals submitted to this task ranged from a frequent attention to mathematical accuracy to a distinctive life-preserving care for people and the environment.

Example 1. Explicitly stating the underlying assumptions of a model:

> *[…] Firstly, it was assumed that the rates for survival and reproduction are the same across years, without any probabilistic variation. […] Change in the local climate, the presence of food and predators, or humans, can occur over the long term; if any of these events have significant impact on the rates, the model would not be able to take them into account.*

In Example 1, the student chose to focus on the validity of the mathematical model proposed in [9] when it is used under the assumption that the survival and reproduction rates of animals are time-independent. In this case, the real-life application of mathematics facilitated the student's conceptual understanding. Example 1 shows evidence that the student was able to evaluate the model by proposing factors (climate, food, or predators) that cause the underlying assumptions of the model to fail. This example is distinctive in that the student did not assume that survival/reproduction probabilities were smooth functions or time, but rather the result of complex interactions between stochastic factors that can be difficult to account for. Most importantly, this example shows that the student was courageous in challenging the stability of mathematical definitions when applied to real life problems.

Example 2. Using modelling and analysis to identify avenues for transformation:

> *[…]the adult survival rate increasing would have the most positive impact on the final outcome after 50 years. This can also be understood in the light of the fact that adults are the only sub-population that carry on to the year after,*

whereas pups and yearlings either grow up and become part of another sub-population or die[…]

Ultimately, it may be impossible to adjust one rate by a specific amount (as was done in the modelling) while keeping the other parameters the same. The behaviour, survival, and reproduction rates are interlinked in a way that makes such a precise controlled intervention implausible. Nonetheless, the rates provide a target that, if achieved, would bring about the non-extinction (and even the repopulation) of the species.

In Example 2, the student held onto the realisation that mathematical models are simplified ways of understanding a reality developed in Example 1. Within this context, the student was able to perform numerical simulations with different parameters and concluded that increasing the chances of survival of adult animals would have the most beneficial effect to the total number of the population after fifty years. This conclusion was closely followed by a disclosure of the practical possibility of changing isolated parameters in the model, where the student recognises that it is often challenging to change single elements of survival in multi-parameter population systems.

Example 3. Humanizing intervention:

> *In real life, [the species] usually lives in pack. The older animals are in charge of the daily hunting while the Pups watches and learns [sic]. In the process of hunting, inevitably, sometimes the livestock of farmers in the area would become the targets. And sometimes, in protecting their livestock, farmers would kill the animal.*

In complex scenarios, such as the one explored in this activity, there is a risk that students take on an approach that is either hostile to locals or to the animals. Although logical, such argument would be limited in that it ignores any complexity in the local reality of human-fauna interaction. Example 3 highlights work demonstrating an ability to draw information from social and ecological sources to interpret an otherwise theoretical mathematical system. In this example we highlight evidence of humanizing approaches towards addressing the challenge. The student identified the importance of hunting for the survival of the species, but also noted the possible issues that arise from spontaneous human-fauna interactions. This discourse is distinctive because it does not seek to demonise either part in the interaction, but rather to objectively state that hunting is a survival mechanism for wild animals and that protecting livestock is also a self-preserving action taken on by farmers.

Example 4. Large-scale non-invasive interventions:

> *Rabies is a disease which severely affects the species as there is no cure for this disease once it's contracted and always results in the death of the animal (Student Reference 1, 2015). One possible method by which animals in an area could be protected […] is through the distribution of vaccines through edible baits (Student Reference 2, 2016). This method of vaccinating animals in the wild is efficient as a*

large area can be targeted and there is a little amount of interaction with humans.[…]

Finally, the student Example 4 highlighted that lethal diseases are a significant threat to the survival of wild dogs, and proposed methods of non-invasive vaccination against rabies through edible baits. The student argued in favour of their proposed solution by considering that an effective solution covers a large area and involves minimal interaction between humans and wild species, basing their argument on references to the literature that had been validated empirically in the past.

4 FUTURE DIRECTIONS

Here, we bring together an envisioned research design to investigate the cross-cultural perceptions of a connected curriculum for critical mathematics from the perspective of student buy-in and motivation when presented with sustainability challenges. This paper does not provide a comprehensive account of a completed study, but ought to rather be viewed as a layout of an envisioned research design, that is initially set forth for the purpose of exchange with the SEFI community.

4.1 Proposed research methodology

We envision to adopt a single embedded case-study design methodology [10] that takes place over two consecutive stages in two different universities, one in Europe and one in Africa. Within the overall study that explores student buy-in to an integrated mathematics framework is a comparative dimension that contrasts the two local case studies, each representing one context of instruction. Figure 1 summarises the overall methodology envisioned for adoption for this study.

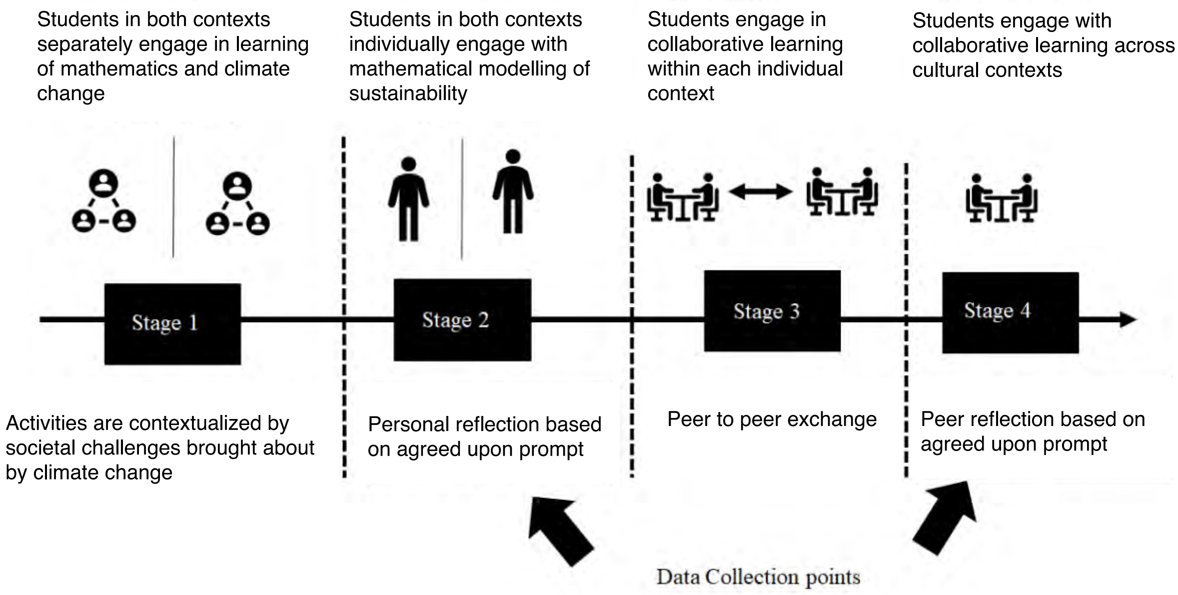

Figure 1. Data Collection Protocol

As presented in Figure 1, students from both contexts will take part in a series of sustainability-focused engineering mathematics workshops and activities in Stage 1. These activities aim to introduce students to critical approaches to mathematical modelling [4-7], sustainable development, and the social impact of engineering. Prompted by agreed upon reflection questions, participants are then encouraged to journal their perceptions about integrating questions of climate change into the mathematics curriculum. Students are prompted to reflect from the perspective of the relevance, complexity, and buy-in. In the second phase of the study, students are presented with an exchange platform that allows them to pair with a peer within their context to exchange experiences with. The peers are then prompted to document their reflections and exchange as guided by a pre-designed framework.

4.2 Proposed analytical framework

Findings from the first cycle of reflection are triangulated against each other and contrasted across the collaborating teams. Repeating patterns within each context are first recorded. This is followed by a cross matching of patterns across contexts. The final level of investigation also includes a triangulation element and a comparative element. Peer reflections are cross matched and re-occurring patterns are recorded. Peer reflection patterns are then cross matched against the individual reflection patterns. Figure 2 illustrates the analytical framework envisioned for adoption.

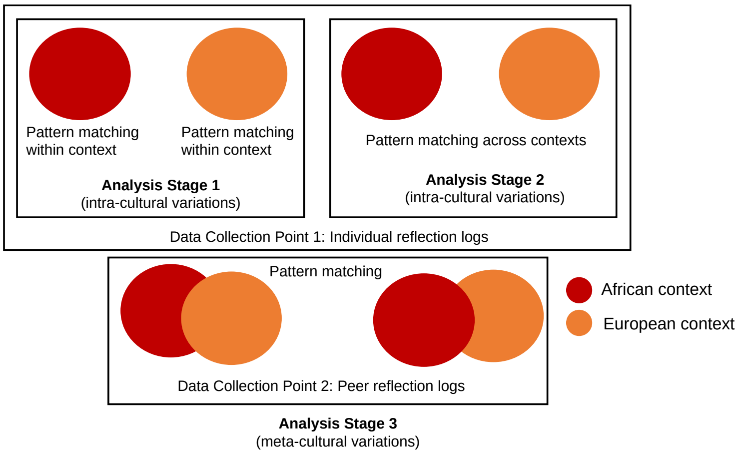

Figure 2. Envisioned Analytical Framework

The investigation therefore adopts an intra-cultural lens, exploring variations of patterns for student buy in within a given culture. It also adopts and inter-cultural lens, comparing variations of patterns across cultures. Finally, it adopts a meta-lens, exploring peer reflections and exchange across cultures.

ABSTRACT

This practice paper describes an ongoing insider action research within the EIT InnoEnergy ecosystem. Its goal is to inspire teaching staff from the seven EIT InnoEnergy double degree Master of Science programmes to integrate Artificial Intelligence (AI) tools and knowledge into their courses based on joint learning. This insider action research runs from 2023 to the end of 2024. In late 2022, a problem statement of 'AI tools for Education' was identified by EIT InnoEnergy teachers as being crucial for their future learning and teaching processes. To align the needs of teaching staff with the complexity of emerging AI tools, a decision was made to plan a hybrid insider action research method. The outcome of this research will be two-fold: one resulting in an AI toolkit covering three teaching staff needs, and two getting a better understanding of the processes involved in taking up a learning innovation at different engineering partner universities spread across Europe within the EIT InnoEnergy ecosystem. This paper shares the first phases of the insider action research and an overview of the individual AI initiatives taken by teaching staff at different partner universities that is the result of a first qualitative data analysis coming from initiatives shared by the insiders (i.e., teaching staff). Action research methodology was chosen to inspire teaching staff to take an investigative and experimental attitude to the new AI technologies while allowing all actors to support each other and grow towards an AI integration in courses and curricula.

1 INTRODUCTION

This practice paper shares ongoing insider action research with professors and teaching staff from the European Institute of Innovation & Technology (EIT) InnoEnergy Master programmes to integrate Artificial Intelligence (AI) tools and knowledge into their Master courses. Action research's distinctive characteristics are that it addresses the twin tasks of bringing about change in organizations and in generating robust, actionable practical knowledge, undertaken in the present tense in a spirit of collaboration (Coghlan & Holian 2023, p. 174).

The recent uptake of AI propels universities as well as societies into a new era of Society 5.0, where "Society 5.0 (Super Smart Society) is a new guiding principle for innovation" (Carayannis and Morawska-Jancelewicz 2022, 3449) in a complex system. Moreover, it gives rise to organic pedagogical models that embrace "freedom within flexible boundaries, richness of possibilities, interconnectedness of all parts of the system, and collective emergence" (Laroche et al. 2007, 74).
The rise of AI also adds an additional layer of complexity to collaborative actions. To ensure the complex texture of bringing together teachers from engineering universities across Europe on a mutually identified problem, a submethod was sought that would fit EIT InnoEnergy's ecosystem's complexity. Insider action research was the best fit. To limit the focus of this paper, only AI initiatives and tools directly used in teaching were investigated and analysed.

1.1 Supporting teaching staff in times of educational complexity

The EIT InnoEnergy Master School offers 7 double degree Master of Sciences (MSc) from top European technical universities and business schools, covering different areas: renewable energy, energy in smart cities, energy technologies, sustainable energy systems, smart electrical networks and systems, nuclear energy, and energy storage. All programmes are taught in the context of innovation, research, and industrial business strategies (van Rijsingen et al. 2023). The EIT InnoEnergy's education strategy and innovation team supports teachers in all partner universities with concrete, contemporary teaching designs and approaches that embrace both innovation and entrepreneurship aspects. In this context, AI knowledge integration happens in a collaboration between teaching staff and education teams set in a multi-university setting, all actors embrace "the importance of distributive leadership in developing a culture of trust and respect" (McGraw et al. 2021, 45). EIT InnoEnergy MSc programmes have the additional complexity of integrating real-world problems in its education through industry projects and challenges posed by industry partners and providing company internships for the students. This additional complex dynamic emphasizes the importance for a "close relation between a university competing internationally and its need to build global trust in the university" (Rosyidah and Rosyidi 2020).

When analysing the opportunities and challenges of AI in this context it was decided to approach this challenge from an action research prism due its suitability to build promotional strategies aimed at building trust (Bogacz-Wojtanowska et al. 2023) 182) showed that "action research projects can be directed towards". In addition, action research is particularly pertinent to current opportunities, issues and changing demands associated with a focus on the *Future of Work*, including sustainability and the natural environment, use of artificial intelligence technologies, and flexible employment (Delany 2022). Moreover, Coghlan et al. (2014) conclude that adding the competency (knowledge and skills) to design, facilitate and lead change by means of insider action research provides added value.

With EIT InnoEnergy particular context, one of the most attractive features of action research was its focus into the opportunity to learn with and from others, through listening and attending, acknowledging differences and assumptions when they are addressing a worthwhile issue (Coghlan and Holian 2023, p. 174). Adding the insider's perspective (the teachers and teaching staff of different academic institutions as well as the educational team), allows all stakeholders to get a voice in the final outcomes of the research. An additional benefit of the insider action research as a method was that insider action research emerged as an important way of understanding and changing organizations (Coghlan 2019; Coghlan and Holian 2007; Coghlan and Shani 2015).

1.2 Emergence of AI within sustainable engineering

While classical engineering has been successful in producing efficient and reliable systems that meet prespecified constraints and prespecified standards of performance in prespecified situations (Mina et al. 2006), integrating AI in sustainable engineering courses has no established prespecified knowledge to base itself on. Due to generative AI solutions only emerging in late 2022, and changing at an immensely high pace, AI related projects need an “engineering approach capable of (1) connecting different areas of knowledge, (2) encompassing diverse aspects of sustainability, and (3) articulating conflicting realities. This approach should allow dealing with situations characterized by uncertainty, emergence, and incompleteness of knowledge and information” (Sigahi, and Laerte Idal Sznelwar 2022, 233) which fits within complexity theory. Moreover, “action research provides the opportunity to study living emergent systems due to the flexibility and adaptability of the research design” (Ollila and Yström 2020, 398).

1.3 Insider target population

The target population of this research is a cross-section of the teachers and teaching staff involved in the EIT InnoEnergy Master school programmes who want to integrate (more) AI into their courses and curricula (n = 32). An open call was launched to all the teachers and teaching staff who wanted to be involved, and it was decided to also keep the target group open, so that during the year additional teachers could join. This aligns with one of the contexts of the insider action research contribution to developing a theory of what really happens in our ecosystem when a new innovative learning tool is taken up.

2 METHODOLOGY

When the complete member base of an organization seeks to inquire into the working of their organizational system to change something in it, they can be understood as undertaking insider action research. (Coghlan & Holian 2023). The context of insider action research is the strategic and operational setting that organizational members confront in their working lives. (Coghlan & Holian 2023). This is actually the case with the emergence and need for including the new AI opportunities within engineering courses and curricula.

The context of insider action research is beneficial within an umbrella organisation consisting of multiple educational partners such as EIT InnoEnergy, since (a) they are real events that must be managed in real time, (b) they provide opportunities for both effective action and learning, and (c) they can contribute to the development of theory of what really goes on in organizations (Coghlan & Shani 2015). The latter option of understanding what really goes on in our teacher organisation allows us to work on a long-term strategy to implement educational change more easily for future learning innovations.
Late 2022, a voluntary group of teachers and teaching staff replied to a call from EIT InnoEnergy's education team on what the teachers found to be their main learning and teaching problem. The teachers and teaching staff identified the problem area as: the understanding, evaluation, and uptake of AI tools by us - teaching staff - to optimize courses and curricula for EIT InnoEnergy Master programmes, in short AI needs in education. This would become the central topic of collaborative research.

As an additional challenge for this research, some of the teachers started experimenting with AI tools and services already. This meant, the group needed to share and discuss relevant data (e.g., first initiatives, research including AI…) of existing AI initiatives within the EIT InnoEnergy university ecosystem, to plan a collaborative action for stimulating AI knowledge and integration in education, as well as in the entrepreneurship journeys. Luckily, action research is a cyclical process, enabling immediate and ongoing optimisation and joint learning. It also allows the researchers to be actors, triggering additional practices and providing an active collaboration with practitioners (Ollila and Yström 2020). With the problem identified, a research initiative was started in January 2023 and running up until December 2024.

2.1 Action Research within sustainable engineering

The collaborative experience derived from an action research process is "designed to inspire an investigative, experimental attitude towards one's own professional practice beyond the organisation of data and the writing process" (Feldman et al. 2018). Thus, a space to share and build on all the teaching staff's experiences regarding AI was created in the form of insider action research. Ensuring a dialogue between all the actors of the target population throughout the research. This motivated EIT InnoEnergy teaching staff to reflect on integrating AI meaningfully in their courses based on the experience. Wood and Butt (2014) emphasised that "all voices are heard and engaged with as new patterns of being emerge". This is why all interested teaching staff was and is invited to instigate or participate in the new AI projects that we research as "action research can offer a positive medium through which to develop emergentist curricula, learning, and assessment approaches" (Wood and Butt 2014, 25).

Insider action research enables to follow the living, emergent system of integrating AI, while providing a research design agile enough to respond to events within our EIT InnoEnergy teaching staff network to create opportunities for joint learning. Thus, the actions, outcomes, and development paths were not planned. Instead, we followed the design as described by Ollila and Yström (2020), stating that actions "emerged as we followed the matters of genuine concern in the collaborative setting" (p. 402).

2.2 Gathering first data: mapping existing AI initiatives

First insights emerged through the continuous dialogue between EIT InnoEnergy teachers and the educational team during educational meetings. As mentioned, the problem statement emerged during a Teacher Conference late 2022. From there, an online dialogue was set up between all interested teaching staff. That dialogue comprised of sharing existing initiatives, as well as emerging challenges, and wish lists regarding necessary AI tools. Aligned to this dialogue between interested teaching staff, the EIT InnoEnergy Teaching Staff newsletter was used to disseminate the existing AI initiatives, as well as the emerging questions that arose. This was done to keep an open, welcoming mindset, allowing other teachers to join the ongoing insider action research.

This understanding enabled the educational team to act flexibly while concretizing the action research cycles of: identifying a problem area, gathering relevant data (e.g., existing AI initiatives – see list below, emerging problems), interpreting data (e.g., teachers identified wishful AI lists, that data was analysed to find patterns), acting on evidence (e.g., re-entering any conclusions to the dialogues), and evaluating outcomes (e.g. if a need for special AI tools were listed, was that in alignment with the needs of more than one teacher). This flexibility includes the continuing "spiral of action research cycles that emerge from the interventions, reflection, and learning after each cycle" (Ollila and Yström 2020, 398), within the overall research design agreed upon with the InnoEnergy teachers to support them with AI tool awareness and integration.

One of the first dialogues on AI tools that happened after the indicated problem, was on identifying the major strands for investigation. A question was launched to all the volunteering teaching staff (n = 32), asking them to share which type of AI support they were interested in. That resulted in three main AI categories:

1. AI tools to support administration (e.g., reporting, proposal writing),
2. AI tools enabling research activities, and
3. AI tools that could be embedded in pedagogical approaches for teaching and learning within engineering for sustainable energy.

During spring 2023, all the existing AI initiatives across the technical partner universiteis of EIT InnoEnergy were mapped. These initiatives were then analysed by all insiders, and reflected upon in group to see whether any of these initiatives would be useful for other members of the teaching staff. The initiatives shared were:

- Learning Analytics projects focused on analysing learner data from courses from the MSc school to inform and improve learning design using AI.
- EIT InnoEnergy teachers' experiments with AI and ethics within their Master courses (ethics, as well as energy and sustainability).
- Initiatives to integrate more digital skills in the curriculum in the form of Data Science and AI courses where students work on real energy problems analysing big data sets and developing e.g., predictive models

(https://www.linkedin.com/pulse/importance-active-learning-data-science-education-empowering/).

- EIT InnoEnergy research on the impact of using AI-generated synthetic video in an online learning platform on both learners' content acquisition and learning experience. A mixed-method approach randomly assigning adult learners (n=83) into one of two micro-learning conditions, collecting pre- and post-learning assessments, and surveying participants on their learning experience. The results show no significant differences in how learners perceived the traditional and synthetic videos (Leiker et al. 2023).
- Projects using AI technology based on Natural language Processing (NLP) to extract AI and sustainable energy skills from job offers, CVs and energy job market reports and be able to map skills to courses available on the market [4].
- And several teachers' exploration of AI tools for several teacher activities (resulting in the 3 identified AI strands to investigate).

From the perspective of the teachers of the individual MSc programmes, we learned that the emerging generative AI presented many new opportunities and insecurities to EIT InnoEnergy's multi-university teaching staff.

3 EMERGING TOPICS AFTER FIRST FULL CYCLE FINDINGS

After following a first cycle of action research: identifying a problem area, gathering the first relevant data coming from the insiders, interpreting that data, acting on evidence, the group had an evaluation after this first cycle. From the discussions three major topics emerged which would be re-entered into the group to set off the next cycle of action research: generative AI and AI tools within our entrepreneurial journey and courses, and emerging AI questions coming from initiatives.

3.1 Generative AI, strategy towards ChatGPT

To create a consensus on how to look like a group to ChatGPT and consequent strategies to take it up or limit its use, an activity needs to be planned where the impact, opportunities, and challenges of ChatGPT4 can be analysed by the group. Ever since the launch of ChatGPT to the wide public late 2022 and the proliferation of other generative AI tools, there has been an explosion of reactions in the education world. Different attitudes could be observed amongst educational institutions that can be categorized, as Philippa Hardman (2023) put it in a TEDx talk, as either dystopian or utopian, with a team "Avoid", trying to keep the technology out of the classroom, team "Ban" convinced that students should be forbidden to use the technology and that plagiarism detection needs to be put in place, and finally team "Embrace" emphasizing the opportunity it brings for the enhancement of educational practice.
Following the words of Saçan, "distrust towards chatGPT is a bad quick fix" (Saçan 2023, 2), and it is our believe that schools and educational institutions should encourage its' exploration so teachers can evaluate and compare uses and potential benefits.

[4] https://aiskills.innoenergy.com/

3.2 Exploring the options of AI within entrepreneurship journey and collaborations with startups and companies

The development of AI tutors and mentors is an area of increasing relevancy for education in general and for entrepreneurship education specifically. Very current examples are Khanmigo[5], a learning tutor embedded in the Khan academy and Yoodli[6], an app giving live feedback on presentation/sales pitch skills. In addition, companies launch AI tools in which ChatGPT 4 makes all business decisions for them (Santos 2023). While adopting such AI tools, teachers must ensure that students understand the impact of decisions based on AI, especially for entrepreneurs who influence society through various economic innovations. Action research incorporating joint learning across teaching staff towards future entrepreneurs is a necessity.

The engineering MSc programmes of EIT InnoEnergy also have an entrepreneurial side to them. Which meant that some of the insiders (business teaching staff) were emphasizing the growing effect of AI in business and entrepreneurship, and the need to explore these applications. AI is revolutionizing the way entrepreneurs are working and the way entrepreneurship can be potentially taught. McKinsey (2022) pointed out that generative AI and ChatGPT-like applications are taking assistive technology to a new level, reducing application development time, and bringing powerful capabilities to nontechnical users. We are already seeing examples of early-stage development of applications in areas such as marketing and sales, operations, IT/engineering, risk and legal or R&D. Specifically in the world of entrepreneurship, we now see public and private investor efforts to use StartupRadar's[7] data and OpenAI[8] to create embeddings, numerical representations of a startup, that allows for quick identification of similar startups (Lorey 2023), tracking of startup performance or tracing of most promising entrepreneurs.

3.3 Emerging AI questions

The ongoing conversations with the insiders, resulted in emerging AI questions containing practical AI use cases for energy engineering education, focusing on opportunities and value increase, while keeping an eye on risks and educational quality:

- Can generative AI tools automate course production such as video creation, content translation and assessment generation reduce the workload for teachers aiming to convert their courses to flipped classroom designs?
- How can students be allowed to use tools like ChatGPT or ChartGPT, for generating code and data visualizations in a way that supports the development of their coding skills?
- How can teachers encourage students to try out tools like ChatGPT to support them as a personal coach in their learning process and assist them in their writing assignments?
- How can teachers use chatbots to support their work such as the creation of lesson plans and generation of good coaching dialogues?

[5] https://www.techlearning.com/news/what-is-khanmigo-the-gpt-4-learning-tool-explained-by-sal-khan
[6] https://app.yoodli.ai/
[7] https://startupradar.co/
[8] https://openai.com/

- Can AI help to trigger ideas and brainstorming, or even create mock-ups for an innovative digital product (see for example [1 AI tool that designs in 1 minute!]).
- How can AI tools support Innovation & Entrepreneurship education, i.e. the more creative processes - traditionally identified as humans' advantage over computers - of ideation, synthesis, customer need validation, product building, and slide creation or pitch structuring for student presentations? How can the tools then be used to **augment** human intelligence and **not replace** human intelligence (De Cremer and Kasparov 2021)?

4 SHARING PRELIMINARY RESULTS AND NEXT ACTIONS

To address the emerging issue of Generative AI, AI in the entrepreneurial journey as well as in education in general, the educational team of EIT InnoEnergy planned an in-person workshop in the autumn of 2023, dedicated to:

- Understanding of the risks and opportunities of generative AI
- Launching an AI toolbox for all teachers
- Adding a focus on AI for its use in entrepreneurial education

Which will lead to the next cycle of the action research aligning it with the spiraling aspect of it described by Ollila and Yström (2020).

5 PRELIMINARY CONCLUSIONS AND ACKNOWLEDGMENTS

Although the action research is ongoing, some first conclusions were captured. A more in-depth understanding of generative AI is necessary, a closer look at entrepreneurial use of AI is requested and needed, and from exploring and sharing AI experiences more AI questions emerged to be addressed. These first cycle findings already highlight the empowering effect of working as a group of insider action research. Not only do the individual contributors grow their understanding of AI, but the group is taken to the next level of understanding by mutual inspiration. Next to redefining foundational knowledge within the teacher group, the skills and attitudes needed to perform key engineering tasks, as well as new skills must be integrated into university programmes.

5.1 Next steps

On 14 September 2023, the next in-person gathering takes place to follow up on this insider action research project. During this workshop, the full AI landscape (including ChatGPT) will be introduced by an AI expert to increase our mutual understanding and discussed by all present to align with the insider action research method. In addition, an AI toolkit will be presented and tested by actors of this insider action research. This toolkit will consist of AI tools useable for administrative purposes, for research support, as well as for teaching and learning (both engineering and business). Based on the outcomes of the workshop, the toolkit will be adjusted and finally disseminated to all EIT InnoEnergy teachers.

5.2 Acknowledgement

This research is supported by EIT InnoEnergy and co-funded by the European Union.

Conference Key Areas: *Addressing the challenges of Climate Change and Sustainability, Engineering Skills and Competences, Lifelong Learning for a more sustainable world*
Keywords: *sustainable logistics, mirco-depot, project-based learning*

ABSTRACT

Sustainable logistics combines the task of the 6R of logistics (right product, right place, right time, right condition, right cost) with social and environmental sustainability, especially low emissions and low resource consumption. This means that a problem that is already challenging, namely planning, executing, and controlling logistical processes, gets even more complex and requires aspects of systems thinking to incorporate environmental and social impacts. Classical approaches of teaching, e.g. lectures with presentations and short exercises on closed problems, do not do justice to the complexity and intricacies of the topic sustainability. In such a context, project-based learning (PBL) where students do group work on open-ended problems with real-world complexity seems to be a more adequate means to teach the subject. The paper describes a PBL course in which students worked on projects to conceptualize

micro-depots for parcel delivery in different areas of Düsseldorf. A micro-depot is a temporary storage location in a city from which parcels can be delivered by cargo bikes. The aim was to locate the micro-depot, design the delivery routes, check the feasibility, and calculate the reduction of greenhouse gases and other emissions. The course was taught in cooperation with a partner from the courier, express, and parcel delivery industry. The paper describes the experiences with the course and gives recommendations for a successful implementation of PBL in courses on sustainability.

1 INTRODUCTION

1.1 Research motivation

Students in industrial engineering learn the basics of logistics in diverse courses such as production management, supply chain management, or operations management. Logistics typically includes the functions of transportation, warehousing, and packaging as well as the processes of purchasing, production, distribution, and reverse logistics, i.e. return and disposal logistics (Deckert 2017, 58-59). The planning, execution, and controlling of logistical processes is usually challenging and complex enough for students and in a classical context does not include considerations of sustainability.

Sustainability adds another layer of complexity to logistics and also forces students to include aspects of systems thinking to incorporate environmental and social impacts. Classical approaches of teaching, e.g. lectures with presentations and short exercises on closed problems, do not seem to do justice to the complexity and intricacies of the topic sustainability. For an elective course on sustainable logistics it was decided to use project-based learning (PBL) where students do group work on open-ended problems with real-world complexity since this approach seems to be a more adequate means to teach the subject. The project task was to conceptualize micro-depots for parcel delivery in different areas of Düsseldorf. This article reports the experiences with PBL in teaching sustainable logistics and gives tentative recommendations for further courses.

1.2 Theory of project-based learning (PBL)

Project-based learning (PBL or PjBL) can be understood as “an inquiry-based instructional method that engages learners in knowledge construction by having them accomplish meaningful projects and develop real-world products” (Guo et al. 2020, 2). Typical characteristics of project-based learning are a driving question, autonomous inquiry and active investigations, collaboration in a team, realism of the problem, and development of a functional solution, usually an artefact such as a prototype or a report with recommendations for action (Kokotsaki, Menzies, and Wiggins 2016, 268; Krajcik and Blumenfeld 2005, 320-328). These characteristics are mainly derived from the fact that students work in teams on a concrete real-world project with different tasks.
According to the PMBOK Guide by the Project Management Institute (PMI) a project is a “temporary endeavour undertaken to create a unique product or service” (Project Management Institute 2021, 4). This means that projects typically have a start and an end, different distinct phases, and a clear and novel goal. Typical features of a project, thus, are time limitation, complexity, uniqueness / novelty, and a distinct set of goals. Such a challenging problem typically leads to a high level of student engagement and motivation (Kokotsaki, Menzies, and Wiggins 2016, 268).

Project-based learning is sometimes grouped together with and in some cases even misunderstood as the concept of problem-based learning, especially since they both share the same acronym. It's true, that both are concepts of learning-by-doing based on autonomy, collaboration, and curiosity. However, there is a distinction between project-based and problem based learning: In project-based learning a well-defined project task is assigned to the team, while problem-based learning evolves around an ill-defined problem without many restrictions. Thus, project-based learning is usually experienced as being more authentic (de Graaf and Kolmos 2007, 5-6). This makes project-based learning especially suitable for learning in mechanical and industrial engineering.

1.3 Sustainable logistics and micro-depots

Sustainable logistics can be defined as the "application of principles from sustainability to logistics, i.e., the functions of transportation, warehousing, and packaging" (Deckert 2020, 1) and includes concepts of both Green Logistics and City Logistics. The task of logistics is the fulfilment of the 6R, i.e. to make the right quantity of the right product available at the right place and the right time in the right condition for the right cost. Green Logistics complements this set of goals with a low resource consumption and low emissions (or two furthers R if you want: right resource efficiency and right emissions). City Logistics focusses especially on the supply of cities and urban areas with goods. Main targets are a low stress on transport infrastructure (e.g. less traffic jams and accidents) and low direct emissions (e.g. noise or particulate matter) (Deckert 2017, 58-64; Deckert 2021, 24-37).

A micro-depot is a temporary storage location in the city – usually a container or a swap body which is dropped off by a truck. From this temporary location parcels can be delivered by cargo bike to the final customers. The micro-depot is typically located at the center of gravity of the deliveries. The logic behind this concept is that it subdivides the last mile into a second last mile (transport of container full of parcels by truck from the depot of the company into the city) and a very last mile (transport of parcels by cargo bike to final destination) (see fig. 1). The transport to the final destination is called a loop which includes several end customer deliveries (Deckert, Stodick, and Hertz-Eichenrode 2021a, 272-273, Deckert, Stodick, and Hertz-Eichenrode 2021b, 550-552, Stodick and Deckert 2019, 237-238).

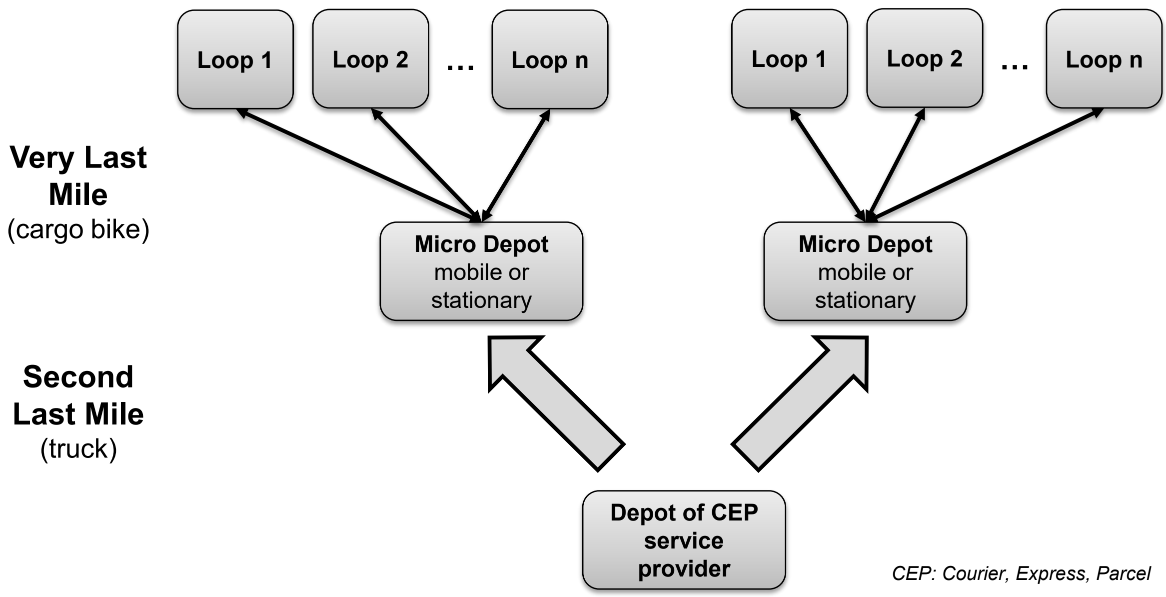

Fig. 1: Concept of micro-depots (Stodick and Deckert 2019, 237)

In this way, the micro-depot combines the advantages of transport bundling with the advantages of environment-friendly transportation and creates necessary conditions for the use of cargo bikes (e-bikes as well as conventional bikes), i.e. delivery of low volumes of goods over short distances. Current research on micro-depots shows that the concept has a high potential to reduce greenhouse gas emissions as well as exhaust fumes and to reduce the strain on the traffic infrastructure in urban areas (Deckert, Stodick, and Hertz-Eichenrode 2021a, 277-279, Deckert, Stodick, and Hertz-Eichenrode 2021b, 553-558).

The challenge to teach sustainable logistics is twofold. First, sustainable logistics is, up to now, not well integrated with classical logistics which focusses mainly on the classic goals of logistical performance (e.g. delivery time) and logistical costs already constituting a trade-off. To this, the dimension of sustainability is added which mainly deals with the externalities of a business and demands a systems thinking approach. Second, sustainable logistics also includes trade-offs between the functions of transportation, warehousing, and packaging, as decisions on the sustainability of one function influences the sustainability of the others (Deckert 2021, 38).

2 COURSE DESIGN

2.1 Target and tasks

As part of the course "Sustainable Logistics" at Hochschule Düsseldorf University of Applied Sciences, students had to work in groups on a project to design micro-depots for parcel delivery in different areas of Düsseldorf. The course was held three years in a row, each summer term from 2018 to 2020. A total of eight groups of three to five participants took part in the course, resulting in a total of 33 participants over the three years. The goal of the course was to locate the micro-depot, plan the supply to and from the depot, verify feasibility, and evaluate the reduction of greenhouse gases and other emissions (see fig. 2).

Fig. 2: Project tasks and sequence

In order to be able to evaluate the results obtained, a comparison was made between the emission output of the micro-depot delivery and the output of the currently implemented variant with delivery by diesel and electric vehicles. The course was conducted in cooperation with a partner from the courier, express, and parcel delivery industry who provided the real-world data to the students. A total of three delivery districts, or "loops" within the company, were defined as locations. The loop "Altstadt" is limited to Düsseldorf's old part of town, the loop "West" to the districts located west of the Rhine, and the loop "Hafen" to the southern part of the city center and the port region. The result of the course was a report with recommendations for action.

The research method of this paper is based on a mixed-method approach where qualitative as well as quantitative data are analysed. The qualitative data are based on the lecturer's perceptions and on an analysis of the final reports of the students. The quantitative analysis is comprised of the comparison of the grades and the course evaluations of the PBL course (2018-2020) with those of the same course with a written exam in 2022.

2.2 Outcomes

Locate the micro-depot

The first aim of the task was to find a suitable location for the micro-depot. The location was found by means of a theoretical and practical location determination. For theoretical determination, the parcel data provided to the students by the logistic partner were converted into individual coordinates using different geocode programs. These coordinates were then transferred to a location map. Next, seven of the eight groups determined the optimal location using the center-of-gravity method. One group determined the optimal location using the Steiner-Weber approach.

Following the theoretical determination, it had to be checked whether it is possible to set up a micro-depot at that location in practice. For this purpose, all groups visited the location to get an idea of the conditions on site. In doing so, they all found that due to various constraints such as pedestrian zones, unfavorable road layout, already developed land, etc., they had to choose a different location nearby in order to determine the practical location of the micro-depot. The geographical difference between the theoretically calculated optimal locations and the possible practical locations for the micro-depos identified during the site visits ranged from 0 to a maximum of 500 meters.

Plan the supply to and from the depot and verify feasibility

The delivery of parcels from the micro-depot to the customers is carried out by e-bikes equipped with an exchangeable box. The box has a capacity of max. 50 packages. Depending on the loop, a different number of e-bikes is required. To calculate the number of e-bikes needed, several factors were taken into account including the maximum working time per employee, the capacity of the box, the maximum range of an e-bike, the calculated distance to the customer, and the time per drop off. To calculate the possible trips per driver, the groups used various route planning methods. Mainly, the groups used the Sweep Algorithm, where clusters are formed first and then the route is determined. Two of the eight groups used the Nearest Neighbor approach for route planning, where the closest customer is served at a time until capacity is exhausted. Based on this planning, the number of e-bikes needed is four to eight e-bikes.

For the supply of the micro-depot, all groups decided to use trucks. The truck delivers the micro-depot in the form of a container. This container already contains the exchangeable boxes, in which the packages are pre-sorted for each tour. This means that the driver at the micro-depot only has to exchange the box as a whole and does not have to load each package individually. For certain deliveries that are impossible or difficult to handle by e-bike, for example, due to unsurfaced roads on which an e-bike can only travel to a limited extent, or when express or large deliveries are involved that require a quick turnaround or a large vehicle, five of the eight groups have designated electric vans for the tours in addition to the e-bikes.

Evaluate the reduction of greenhouse gases and other emissions

After completing the route planning, the students had the task of finding out whether energy consumption and emissions could be reduced by using the micro-depot. For the calculation of energy consumption and greenhouse gas emissions, DIN EN 16258 was used. In the first step, the transport performance was divided into individual legs. Then the energy consumption and emissions were calculated for each leg. In the final step, the results of all legs were summed up. For the evaluation of the carbon footprint, calculations were performed in the different variants of (1) standard delivery with diesel delivery vehicles, (2) standard delivery with electric delivery vehicles, and (3) delivery with the use of micro-depots and e-bikes. The result for all groups shows that when using the micro-depots, both greenhouse gas emissions and other emissions (e.g. exhaust fumes) are the highest for transportation with diesel delivery vehicles followed by delivery with electric vehicles. The highest savings can be achieved using the micro-depots.

All in all, the analysis of the outcomes from 33 students in the summer terms 2018-2020 shows that there was a high student engagement – as indicated by the self-reported motivation in the course evaluation and the attendance quota during lectures. No student failed the course, the average grade was 91% with a span of 77%-100% which is above average.

3 EXPERIENCES & RECOMMENDATIONS

3.1 Experiences

The experiences of teaching the course three years in a row show some advantages and disadvantages of project-based learning (PBL) which are mainly in line with what can be expected from the theoretical concept. The main advantages are as follows:

- PBL offers the opportunity to combine the theory of a subject with a practical part, e.g. the theoretical calculation of a center of gravity for a location and the practical search for an appropriate space for the micro-depot in the real world. This offers a deeper learning experience for the students, as they are forced to translate their findings into reality with all the related decisions necessary to accommodate for real-world restrictions. The combination of theory and practice in PBL also shows students the need for compromises in real-world situations. A theoretical calculation is never a perfect solution, as it is based on certain assumptions and cannot take all real-world restrictions into consideration. So students experience that there is no cure-all or silver bullet, but that theory gives good approximate solutions which can serve as a starting point for the practical solution. They also learn that there is no one-size-fits-all solution, again requiring compromises, e.g. some deliveries, especially big ones, still have to be made with a classical delivery vehicle, as they are not feasible with a cargo bike.
- In a PBL course on sustainability, students not only learn new methods (e.g. calculation of greenhouse gas emissions), but they also learn that standard methods of logistics (e.g. methods for vehicle routing) make a valuable contribution to sustainable logistics. It is the integration that matters.
- A project with interlinking tasks can only be solved through collaboration which means it requires a good deal of social interaction and a functioning team. Thus,

besides functional competence in logistics and sustainability, students gain social competence in a PBL course.

The main disadvantages of a PBL course in sustainable logistics are as follows:

- As PBL focusses on one specific project, students do not get a good overview over the topic (e.g. sustainable warehousing and packaging were not part of the course which focussed on micro-depots), and not all necessary methods and trade-offs can be included. So the breadth of knowledge which students acquire is rather limited. This contrast became clear when the course was taught to a larger group of students using a written exam as the method of examination in 2022: Students gained more breadth of knowledge but sometimes lacked in depth of understanding.
- A PBL course means more effort for the lecturer than a standard course. Main efforts occur in the design of the project, the preparation of the excursion to the industry partner, and the coaching of the teams. As the solutions to open-ended problems might vary, the grading also demands more instinctive feel than e.g. grading exercises or exams with closed problems. Furthermore, the success of a PBL course depends to a large part on the industry contacts of the lecturer.
- An important prerequisite for the students who want to participate in a PBL course about sustainable logistics is that they need to be well acquainted with the concepts and methods of classical logistics. The course only teaches sustainability aspects of logistics content-wise.

Student behaviour and feedback mirrored these advantages and disadvantages (as expected from the theory on PBL):

- In the three years when the course was taught in the PBL format there was a high student engagement and motivation. No student failed the course and the average grade was relatively high. Engagement and grades were distinctly lower when the course was taught with a written exam as method of examination in 2022.
- The students reported that they gained a deeper understanding through the course, but some criticized the lack of an overview over the subject or specific topics of interest.
- The course demanded social competence through team work due to the interlinking steps or tasks. The groups with the weakest team spirit – visible through bickering in the team or incoherence in presentation style – usually delivered the worst results and got the lowest grades.

3.2 Recommendations

From our experiences we generated three recommendations for problem design suitable for a PBL course. In accordance with the 6R of logistics we called them the 3R of PBL:

- Right topic: To get a driving question which motivates the students, the problem needs to be based on real-world data about an interesting topic and divided into interlinking tasks that force students to collaborate.
- Right partner: A realistic problem for a PBL course requires an industry partner who is willing to share data, talk openly about business intricacies, and give feedback on the students' solutions.
- Right limits: In the design of the problem there is a trade-off between realism and effort: The problem needs to be realistic enough to be motivating, but needs to respect the time and capacity limits of a semester course. Furthermore it

needs to be neither too specific for students to get lost in details nor too broad for students to lose focus. If the solution is implemented by the company, the damage potential of the solution needs to be kept low.

4 SUMMARY AND ACKNOWLEDGEMENTS

In summary it can be said that project-based learning (PBL) offers the opportunity for a deep learning experience of the students in sustainable logistics and significantly improves engagement and outcomes of the course. However, there are three caveats to be taken into consideration. First, there is a tension between breadth and depth of learning. PBL lacks in conveying the breadth of a subject. A combination of traditional courses with PBL courses would be an optimum solution, but often fails because of time restrictions. Second and related to the first point, when teaching sustainability there is the challenge of more and more additional contents which requires lecturers to re-examine their contents and set a new focus to keep within the time restrictions of a course. Third, up to now there is no real integration of classic and sustainable logistics which are usually taught in separate courses. This shows that sustainability – important as it is – is still often perceived as an add-on to classical logistics. Time will tell if such an integration will be possible in the future.

The course was taught with the support of Klaus Stodick, Advisor City Logistics/ESG, at United Parcel Service (UPS) in Germany. The authors would like to thank Mr. Stodick and his team for their support.

ABSTRACT

There is strong support for ensuring all university students have an option to undertake relevant work placement. Work-placements enable students to engage with enterprise and develop experiential learning while linking their academic study and theory to real industrial practice. Such placements, or internships, offer students an opportunity to build their self-confidence while refining their transversal skills such as creativity, innovation, communication, team-working and problem solving. Furthermore, placements broaden students' knowledge base and improve their employability upon graduation.

While student cohorts benefit from engaging with enterprise the enterprise also benefits, such as from the energy, new perspectives and ideas interns can bring to the workplace. Multiple models (such as professional apprentices and Earn and Learn models) highlight the importance of this symbiotic relationship. The need to support

[1] *Corresponding Author*
KD Delaney
Kevin.delaney@tudubin.ie

and expand work placement opportunities to benefit all graduates is also a key element of government policy. Supporting this ambition and reflecting changing student profiles, employer expectations and the nature of work, there is a need to re-imagine the traditional understanding of work-placements to safeguard talent pipelines and increase graduate employability.

A concise literature review of existing work placement models is presented. This is followed by a description of the approach developed by the Enterprise Academy within Technological University Dublin to help students achieve learning outcomes typically associated with work-placements in a new, innovative and sustainable way. The approach described was successfully piloted for 2 student cohorts during the Covid pandemic. It highlights the value of redefining traditional placements for students, enterprise and higher education providers.

1 THE IMPORTANCE OF EXPOSURE TO ENTERPRISE AND WORK PLACEMENTS FOR GRADUATE FORMATION

Exposure to enterprise is crucial for university graduates as it provides them with the opportunity to apply and refine their academic knowledge while simultaneously gaining real-world experience. This exposure equips graduates with practical skills and knowledge that are highly relevant in today's competitive job market. More specifically, graduates develop transversal skills in areas such as project management, teamwork, creativity, communication, problem-solving, and critical thinking, which are highly sought after by employers. This practical exposure also helps graduates to understand how businesses operate, including their structure, processes, and challenges. Furthermore it provides them with a realistic understanding of the working world and instils confidence in them regarding how they can successfully interact with it.

The importance of work experience and how it provides graduates with key practical, transversal skills to help them bridge the gap between academia and the real world, enabling them to become well-rounded professionals, is recognised. In doing so graduates expand their professional network, and cultivate an entrepreneurial mindset. Giving students the opportunity to engage in work placement also aligns both with Irish Government policy [1] and the advice from professional bodies such as Engineers Ireland, highlighting the need for universities to prioritize providing opportunities for exposure to enterprise as part of students’ formal education. Section 2 summarises existing approaches to work placement from the literature and the need for alternative approaches. Section 3 describes the way that we re-imagined work placement and piloted it during Covid. Section 4 summarises the results of our impact analysis and summarises the lessons learned from our pilots. Concluding remarks are presented in Section 5.

2 LITERATURE REVIEW: THE NEED FOR ALTERNATIVES TO TRADITIONAL WORK PLACEMENT

The key concepts of Work Based Learning (WBL) where learning occurs in the work environment, and Work Integrated Learning (WIL) where learning is intentionally integrated with the practice of work, are differentiated in the literature [2]. Placements, where students are physically based in the workplace for a specific time period, have traditionally been the most common approach for fostering engagement between enterprise and education. This traditional work placement model may not be accessible to all students, particularly those facing financial constraints, geographical limitations, or other personal circumstances. Work placements can also be concentrated in urban areas, making them inaccessible for students who live in rural or remote regions or who might find it difficult to secure appropriate and affordable accommodation away from their usual place of residence. Business cycles can also limit the number of work placement opportunities available at certain times and this risk must be mitigated and alternatives considered.

Considering the shortfall of opportunities for placements and internships and factors that impede some students from committing to being physically based in the workplace, there is a need to explore alternative approaches [3,4,5]. Increasing attention has therefore been given to alternative formats which fall under the umbrella term of WIL, namely, hackathons, simulations, role modelling, site visits, enterprise projects and other experiential learning projects that prioritise the development of discipline-specific competencies related to professional practice and transversal or soft skills [2,3,4,6,7]. WIL intersects theoretical and practice learning and essentially brings real world work experiences into the classroom. It encapsulates the broad spectrum of enterprise-student engagement practices [7]. These new models can provide opportunities for students to work in cutting-edge industries, emerging fields, or unconventional career paths where opportunities available might align more appropriately with students' interests or expectations.

Whether it is WBL or WIL, the value is evident and is outlined extensively in the literature [3,4,7,8,9]. Benefits include the development of employability skills and work readiness [2], the fostering of career managing competencies such as professional networking, labour market understanding, informed career goals [8] and advancing transversal skills such as teamwork, problem-solving & decision-making.

The basic premise for both WBL and WIL is that not all skills can be learnt in the classroom or workplace but through a combination of both [2]. Affording students the opportunity to interact with different practitioners in a company though WBL or WIL initiatives requires a sophisticated level of both technical & non-technical skills [6]. Through the provision of authentic learning experiences to students across their learning journeys, the goal is to help students successfully and confidently transition to work. Having an increased clarity of their career expectations will improve their chance of success upon graduation.[3,4]. Such integration of theory and practice to directly support students' career readiness is a powerful learning approach [4]. Work-based experiences are essential to prepare students for the real-life context of their professional practice [6].

Students value the opportunity to engage with enterprise and develop an understanding of their proposed career through both traditional and non-traditional placement experiences [4,8]. Students cite the value of working with others and having unique experiences focussed on work related tasks as key to success when entering the workplace [10]. The more holistic approach is deemed necessary to ease students out of their comfort zone and face the emotional challenges within the work environment [10], helping students refine their transversal skills. Upon completion of a WBL or WIL programme, students reported the benefits of having an increased ability to identify their capability gaps and better synthesise their strengths and motivations [8].

The literature highlights that students require more WIL opportunities as they realise the benefits in terms of both skill development and the fact that practical experience is such a high priority among graduate employers [3,5]. The pilot programme discussed in section 3 addresses this and confirms the positive impact of WIL for all students.

Graduate employability is one of the fundamental issues influencing the missions of Higher Education Institutions (HEIs) [6] and they strive to find ways to enhance student employability. The importance of adopting a more holistic and skills-based approach to developing employability is well documented in the literature [10]. The need to go beyond the skillset that can be taught and learnt solely in a classroom and adopt a more integrative approach to boosting employability is a top priority in HEIs [2,3,7,10]. Educational institutions, academics, employers, and even policymakers must consider alternative work placement options that provide students with more flexible, adaptable, diverse and potentially more inclusive pathways to gain real-world experience and enhance their employability.

Reedy et al. document a case study where engineering students embarked on a project oriented, problem-based learning (PO/PBL) WIL learning activity to increase their workplace awareness and boost their work-readiness capabilities [5]. Students were tasked with solving a unique enterprise challenge requiring both technical and non-technical skills for its resolution, meeting with both enterprise and academic mentors weekly to discuss their progress [5]. The study revealed the value of this model for boosting students' professional identity, motivation and providing useful opportunities for students to develop employability skills in a supportive environment.

The Sustainable Innovators for Enterprise (SIE) programme documented here adopts a similar approach by facilitating a space for students to engage with the world of work via an enterprise challenge. The SIE programme prioritises the development of employability and transversal skills through the lens of a global, cross-disciplinary enterprise challenge with an international dimension. It supports the need for more innovative and sustainable models to ensure students receive meaningful opportunities to prepare for their future careers. The remainder of this paper details the SIE work placement programme, built upon research conducted prior to the Covid pandemic, that highlighted the need for such alternatives. This programme was piloted during the pandemic as an alternative to traditional on-site work placements.

3 STRUCTURE OF THE ALTERNATIVE TO WORK PLACEMENT PILOTS

The work placement programme was structured to mimic a traditional work placement which would meet the requirements of our existing programmes. This programme was available to students across the university and also to international students from Hainan University who are registered on TU Dublin programmes. Student interaction with the programme can be viewed as part of four key phases.

Table 1. Key program activities of program as piloted

Phase	Key Activities	Duration
Phase 1: Introduction SIE Onboarding	Innovation Onboarding Create Confidence Workshop STLR Training Introduction to Cultural Intelligence Enterprise Challenge Day	~ 1 week
Phase 2: Pre-immersion Enterprise Recruitment Kick- Off Session	Recruitment Training Indeed Workshop Indeed Live Hiring Event: Student Interviews for Enterprise Challenges You Got the Job! Student Teams Assigned TU Dublin & Enterprise Mentoring Kick-off Meeting	~ 1 week
Phase 3: Project Immersion Supporting modules Key Project stages (Innovation Lifecycle)	Innovation for Enterprise Global Citizenship in the Workplace Creativity & Human Centered Design Future-Proofing Talent 1. Empathy & Problem Definition 2. Investigate, Human Centred Research and Empathy 3. Ideate, Evaluate and Prototype 4. Build it and Test it 5. Iteration and More iterations 6. Implementation Part 1 7. Implementation Part 2	~ 10 weeks
Phase 4 Post-Immersion	Final documentation and pitch	~ 1 week
Innovation Conference		End of programme

a) Recruitment to a particular challenge

As part of Phase 1, each enterprise presented details of their company and proposed their challenge(s). Following this, students had an opportunity to ask some initial clarification questions relating to the enterprise and/or the challenges. Subsequently students applied to undertake a particular challenge. For Phase 2, the Enterprise Academy partnered with Indeed to pilot their Indeed Hiring Platform (IHP) to simulate a real-world recruitment process. The Enterprise Academy worked with the IHP team to design a recruitment process that was suitable for the student cohort. The enterprise challenges were then posted on IHP and students had the option to select their three preferences. Students then completed a pre-screening questionnaire to assist with determining their suitability for challenges.

The SIE design focused on immersive experiences whereby Indeed hosted an online hiring event over two days. Students were invited by Indeed for an online Interview through the virtual hiring platform. The programme team worked with Indeed to design specific questions and an interview style suitable for the student cohort. Indeed provided several trained recruiters who conducted one-to-one interviews with students. A matching algorithm was used to match the most appropriate students with the challenge most appropriate to their skillset, Students were then “offered the job”. The programme team, Enterprise Academy and Indeed collaborated to ensure each team was composed of the multidisciplinary skillset required for each enterprise challenge. This was part of a detailed process to help the students develop their own career readiness skills. Examples of activities covered include interviewing skills, self-promotion, and building their own profile on Indeed and LinkedIn.

b) Modules

This programme was assigned a total of 30 ECTS credits, matching traditional placement ECTS allocation. The breakdown of this was three five-credit modules and a fifteen-credit Enterprise Challenge module. The modules were co-created with enterprise and academic expertise. Each five ECTS credit module was designed to help students develop transversal skills and support their attempts to follow a systematic design methodology in responding to their design challenge.

Fig. 1: Overview of modules involved in work placement as piloted

Flexibility was designed into the approach to enable students from other programmes, or in part-time placements, to also take individual elements. For example, students who could only secure part-time placements completed the 15 ECTS to scaffold their experience. This modular and agile approach addressed a strategic goal of the university to create economies in module design and delivery.

c) Teaching approach

Each team combined students from TU Dublin and Hainan University resulting in an international, cross-disciplinary experience for all. The virtual exchange model provided an immersive global learning experience for participants bringing diverse students and faculty together across borders of time zones, language, culture and disciplines. The Global Citizenship in the Workplace module was co-created and delivered by faculty from Hainan and TU Dublin exposing students to culturally diverse teaching strategies and providing a rich insight into Chinese culture.

The Enterprise Academy advised on best practice for simulating an immersive work environment. The learning environment emphasised creating 'brave spaces' [11] that fostered creativity. Students engaged with a variety of professional tools such as Mural, Cultural Intelligence Self-Assessment, and strategies such as Wicked Problem Solving and Human Centred Design to facilitate an immersive work experience. Consequently, transversal skills such as wicked problem solving, Cultural Intelligence (CQ) and leadership were developed in a simulated a workplace training and development environment.

d) Role of academic and enterprise mentors

Each team was assigned an academic and an enterprise advisor or mentor to help and guide the teams through weekly meetings. The enterprise advisor was from the organisation who assigned the challenge and were able to answer questions from a customer organisation perspective. The Enterprise Academy partnered with Active Peers AI and internal educational developers to design the SIE mentoring process. Students were expected to arrange the meetings, set an appropriate agenda, take meeting minutes and actively manage the meetings to ensure that all questions that they had were dealt with and answered appropriately within the allocated time slot.

e) Assessment and deliverables

The supporting modules and the Enterprise Challenge were assessed separately and involved different deliverables. The Enterprise Challenge had formative and summative assessments. Students created a portfolio explaining their proposed solution and gave a live pitch to an assessment panel and answered questions in a formal question and answers session.

4 PILOT STUDIES: IMPACT ANALYSIS RESULTS AND LESSONS LEARNED

The two pilots provided insights from a student development and university enterprise engagement perspective. The programme team collected data and observations throughout the pilot design and delivery. Insights collected focused on informing the pilot design and the observations enabled the team to identify areas for student transformation. Prior to commencing SIE all students participated in an interactive workshop to self-identify their personal strengths and areas for development. These workshops utilised human-centered design (HCD) techniques and enabled the programme team to identify student concerns and areas for development. For example, in both pilots the interview process and confidence in collaboration were identified as areas of concern and as development opportunities. The lessons learned from the first pilot informed the next iteration and the recruitment process was evolved to ensure the students were supported and that the development opportunity was leveraged. Fig. 2 provides an example of the HCD technique Hopes and Concerns applied with the 2021 pilot cohort.

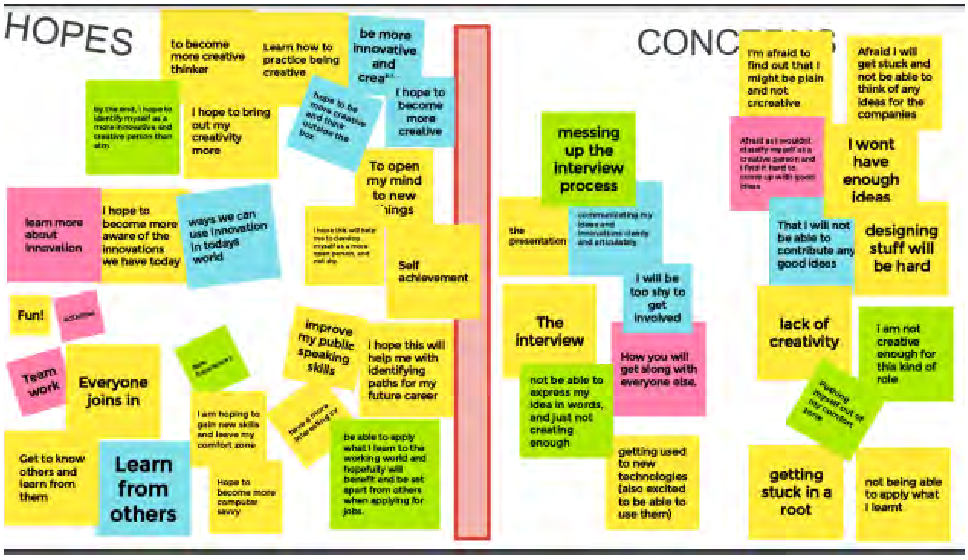

Fig. 2: Pilot 1 Observations 2021, Hopes and Concerns

The student feedback post-pilot presented insights that suggested a positive impact on student development and that SIE was successful in preparing students for the workplace. Table 2 lists a selection of responses demonstrating pilot impact.

Table 2: Positive Insights from Student Feedback

Question	**Response Rate**
I feel more prepared for the workplace	37.5% strongly agreed, 37.5% agreed
I feel more confident in my communication capabilities	50% strongly agreed, 50% agreed
I feel more confident in my team working capabilities	62.5% strongly agreed 32.3% agreed
Rate your experience of enterprise engagement on SIE	68.8% excellent, 25% very good
Rate your experience of the SIE mentoring programme	50% excellent, 37.5% very good
Rate you experience overall on SIE	Average of 4.19 out of possible 5

The main barriers identified for SIE were perceptions of *work placement alternatives* and *resource constraints*. The programme team observed that faculty and students viewed the 'alternative placement' as an option for students that could not secure a traditional placement. This view of SIE as a lower value experience would need to be further explored and the impact of SIE on skill development validated through a larger sample. The pilots discussed in this paper received funding to explore technology and professional resources to emulate the work environment.

5 CONCLUDING REMARKS AND FUTURE PLANS

There is strong support for ensuring that all university students have an option to undertake relevant work placement as part of their studies. The lack of accessibility, and potentially availability, of suitable work placements, can limit student opportunities and hinder their ability to gain practical experience. This will require universities to have alternative work placement model options available for their students.

These alternative approaches to work placement can encourage students to explore new areas of interest and can provide them with more flexibility and adaptability in gaining real-world experience while they develop unique skill sets. These new ways of learning and skill development will make them more competitive and adaptable in the ever-changing job market.

The world of work is evolving rapidly and new industries, technologies, and career paths are emerging while non-traditional work arrangements such as remote work, freelancing, and the gig economy are becoming more prevalent. Traditional work placements may not provide students with exposure to the latest trends and innovations, which could potentially impact their readiness for the job market

The lessons learned from this pilot and existing research suggest that students benefit from the opportunity to work in a multidisciplinary environment. Higher education providers have the opportunity to create these immersive environments. However, if the intent is for these environments to prepare students for the workplace then further collaboration with enterprise is needed. This collaboration has purpose for enterprise and can provide many benefits including, access to talent pipelines, insights and research.

There is a need for HEIs to reflect and ask the question 'how are we preparing our students for work?' The answer will require further collaboration with enterprise to co-create education offerings that reimagine the concept of ‘close to practice’ or 'approximations of practice' [12]. It is hoped that the pilot described here might contribute to the development of flexible and engaging alternatives for students.

ACKNOWLEDGEMENTS

The authors acknowledge funding made available to the Enterprise Academy of TU Dublin through the Convene project, funded by the Irish Government’s Human Capital Initiative under Pillar 3, which facilitated part of the work presented here.

Problems without Solution? Challenges of Climate Change and Sustainability in Engineering Education

S. Dornick[1]
Technische Universität Berlin
Berlin, Germany
ORCID

Conference Key Areas: *Addressing the challenges of Climate Change and Sustainability, Equality, Diversity and Inclusion in Engineering Education*

Keywords: *Sustainability, Gender, Diversity, Engineering Education, Teaching Methodology*

ABSTRACT

The issues of climate change and sustainability are urgent and critical concerns of our time. The rise of climate disasters, such as floods, droughts, forest fires, and hurricanes, poses a threat to the survival of humans, animals, and plants. Despite scientists having warned about the impending dangers of high CO2 emissions, particularly from the global North for many years, there has been no political or technical solution in sight.

Engineers are known for being problem-solvers, but what happens when the problem is complex and the consequences of technical interventions are hard to predict? In my paper, I propose measures to sensitize engineers to the complexity of climate change and sustainability. Based on the method of focused ethnography, I draw on Feminist teaching methods, my extensive teaching experience in the field of transdisciplinary gender research in science and technology studies, and my observations during the international "Winter school of ENHANCE on gender and diversity in science, technology and society" at Technische Universität Berlin in 2023.

[1] *S. Dornick*
s.dornick@tu-berlin.de

The paper concentrates on the content and pedagogical approaches that can be used to convey the complexity of the issue while fostering the development of critically reflective knowledge. By incorporating these measures, engineers can be better equipped to tackle the challenges posed by climate change and sustainability in a more holistic and thoughtful manner.

1 INTRODUCTION

1.1 Climate Change and Engineering's Impact on Sustainability

Climate change has altered the Earth's climate system over the past two decades, resulting in long-term shifts in temperature, precipitation patterns, and extreme weather events. Greenhouse gas emissions from human activities, such as burning fossil fuels and deforestation, are the primary cause of climate change. These emissions lead to increased concentrations of carbon dioxide, methane, and nitrous oxide in the atmosphere, resulting in a warming effect known as the greenhouse effect. The impacts of climate change are severe. Over the past two decades, climate change has continued to intensify, leading to more frequent and severe extreme weather events and significant environmental impacts such as melting of glaciers and ice sheets, coral bleaching, and declining fish populations. However, there has also been increased awareness and action to address the issue, including the adoption of the Paris Agreement and measures to reduce greenhouse gas emissions and increase climate resilience.

In light of these facts, it must be stated that climate change poses a significant threat to the long-term sustainability of human societies and natural systems. Considering this, sustainable practices such as transitioning to a low-carbon economy, adopting sustainable energy sources, sustainable land use practices, sustainable transportation options, and sustainable manufacturing practices are crucial for reducing greenhouse gas emissions and ensuring the long-term sustainability of human societies and the natural environment.

Addressing climate change and sustainability in Engineering Education provides an opportunity to create a more sustainable and resilient future for people and the planet. Because sustainability and engineering are closely intertwined since engineers have a significant responsibility in designing and implementing solutions that advance sustainable development. With their knowledge and expertise, engineers can create technologies and infrastructures that minimize environmental impacts, conserve natural resources, and enhance social and economic conditions. Renewable energy technologies, such as wind, solar, and hydro power, are a crucial area where engineering can contribute to sustainability.

1.2 Gender, Diversity and Sustainability

Gender and diversity are important but nevertheless still under-thematized dimensions of climate change (Buckingham/Le Masson 2017). Not only are women predominantly engaged in the main energy-consuming tasks in the home, but gender and diversity also play a role at the sociocultural and technological levels. To this end, it is necessary to develop a broader perspective with respect to sustainability and to sensitize students to the (gendered) impact of their technological solutions. In the following, I list key points that have been largely ignored in technology research on climate change:

- A binary notion of gender makes it impossible to include queer, non-binary identity designs that cannot be easily categorized in adaptive designs. At the same time, queer people often live in areas threatened by climate change due to their social stigma.
- Intersectional analyses of the implementation contexts of technological solutions are indispensable to adequately consider the particular inequalities that for example affect women of color.

- Women, in particular from the global South, are often portrayed as victims in discourses on climate change. This perspective overlooks the fact that women form a heterogeneous group that is permeated by further dimensions of inequality. At the same time, the focus on women (from the global South) narrows the view.
- The important role that constructs of *white* masculinity play in determining individuals' carbon footprints is often overlooked.
- Studies show that women in leadership positions are responsible for implementing more sustainable solutions. However, most leadership positions are held by *white* men.
- At the same time, women are less likely to be involved in adaptation strategies and processes to develop technological solutions to climate change, as they are often unable to engage in participatory processes due to caregiving responsibilities.
- Technological solutions can profoundly change the lives of girls and women and, in the worst cases, help to re-stabilize asymmetrical gender relations.

As I mentioned elsewhere (Dornick, 2021), it is important to note that brief exposure to diversity and inequality issues may not sufficiently equip students with the ethical capabilities required to develop technological solutions for complex societal problems. To address this, Engineering Education should also aim to deepen students' understanding of power dynamics in society by teaching them about the gendered nature of technology and how power relations are manifested in material forms. The inclusion of gender and diversity skills in Engineering Education not only prevents exclusion and discrimination, but also promotes successful and sustainable engineering by rejecting individualistic approaches and the predominance of male professional cultures. To equip future engineers with the ability to address the intricate environmental, social, and economic challenges of our world, it is essential to teach sustainability in Engineering Education.

2 METHODOLOGY

2.1 Research Design

In the following I draw on the method of ethnographical observation. Ethnography is an approach to qualitative research that is used to investigate cultures and people (Flick 2007). It involves the systematic observation of social phenomena where researchers immerse themselves in the culture they are studying to gain an insider's perspective. Ethnography employs various data collection methods, such as participant observation, interviews, focus groups, and document analysis. The purpose is to gain a deep understanding of the culture from the perspective of those being studied, and to document the social and cultural practices and norms of the community. Ethnography is commonly utilized in disciplines such as anthropology, sociology, and other social sciences to study a broad range of subjects, including culture, social interactions, and power dynamics.

For the following study, I have oriented myself on the method of focused ethnography (Knoblauch 2001). Focused ethnography is a type of ethnographic research that focuses on a specific research question or phenomenon within a particular community or culture. It is often used when researchers have a limited amount of time or resources to conduct their research. Focused ethnography differs from traditional long-term ethnography in that it has a narrower scope and is conducted over a shorter period of time. The researcher may use a variety of qualitative data collection methods, such as interviews, observations, and document analysis, to gain an in-depth understanding of the specific phenomenon or research question. The findings from a focused ethnography study can provide valuable insights into the social and cultural practices of the community being studied, and can be used to inform future research and interventions. At present, ethnographic methods enjoy great popularity, especially in the social science-oriented areas of science and technology research, because they make it possible to take a detailed look at the practices of the making of reality.

2.2 Research Field

As a research field, I take as a basis my own extensive teaching experiences in the field of transdisciplinary gender research in science and technology, my observations during the international "Winter school of ENHANCE on gender and diversity in science, technology and society" at the Center for Women's and Gender Studies (ZIFG) at Technische Universität Berlin (TU Berlin) in 2023, as well as my analysis of learning journals of students in Engineering Education that had taken part in the learning module "Bue Engineering" at The Department of Machine Systems Design at Technische Universität Berlin (Dornick 2021). The main objective of "Blue Engineering" is raising awareness among students about their social and ecological responsibilities. This elective module has been available since 2011 and is worth 6 credits points in Mechanical Engineering, Information Technology in Mechanical Engineering, Transportation Engineering, Sustainable Management, and Industrial Engineering degree programs. Every semester, approximately 80 students participate in the four-hour seminar. Over the years, this module has been successfully adopted by other universities, including Hamburg University of Technology, Düsseldorf University of Applied Sciences, Berlin University of Applied Sciences, and Ruhr West University of Applied Sciences.

The faculty of "Humanities and Educational Sciences" at TU Berlin has a close association with the four faculties for technical and natural sciences, owing to the university's distinctive history (Profile "Humanities and Educational Sciences at TU Berlin", 2023). The ZIFG, following an interdisciplinary teaching approach, offers courses that are open to students from humanities and educational sciences, as well as technical and natural sciences. Students can earn ECTS points towards their BA and MA degrees or participate in specialized programs, such as "Gender Pro MINT" or ZIFG's gender certificate.

The courses observed in this study were taught by the author during the period from Winter term 2018 to Winter term 2023. The author mainly conducted participatory observations during class sessions. Evaluation was carried out during the last class of the term when each student provided oral feedback. The main focus of these courses was to enhance Engineering students' ability to act in a gender-sensitive and diversity-oriented way by deepening their understanding of intersectional forms of discrimination and co-constructive processes of gendering artifacts. The curriculum included topics such as Feminist philosophy and critique of science and technology, introduction to transdisciplinarity of gender studies in science and technology, gender, diversity and sustainability, and gender in Higher Education. Participants in the courses had diverse academic backgrounds, including "Engineering," "Computer Science and Design," "Culture and Technology," and "Gender Studies." The size of the classes varied from five to 35 participants. I consider both face-to-face and online courses. For synchronous sessions, the video conferencing tool Zoom was used. All sessions were assisted by an e-learning platform and, from 2020, also received support from various other online tools such as online pads, Wonder (a platform for working in working groups), Discord (a platform for meetings and chats), and online whiteboards (see Dornick 2020, for a detailed description of the module “Blue Engineering” and Dornick 2021 for a detailed description of my teaching practice).

3 RESULTS

3.1 Understanding Climate Change as a Complex and Multi-faceted Phenomenon

Let me start with an anecdote. In my presentation on Gender, Diversity and Sustainability at the international “Winter school of ENHANCE on gender and diversity in science, technology and society” at TU Berlin, I drew attention to the urgency of climate change and the need to take appropriate action to address it. The international students nodded, studied the overviews, and actively participated in the discussion session that followed. After a while, one student asked, "And what proposal do you have now for solving climate change?"

I resort to this anecdote for several reasons. First of all, because I was so surprised by the student’s question that this moment has impressed itself on me. Moreover, this anecdote seems to me like a vignette in which the difficulties and challenges of inter- and transdisciplinary understanding on climate change are revealed.

How on earth, I wondered, could students assume that one person, let alone me, a sociologist from Feminist Science and Technology Studies, could have found THE solution to climate change? But besides the naivety of the question, I also felt something like hope in that question. Hope, that there could be a solution, that it could be found, even that it had already been found. I looked into the room, which was filled with prospective engineers, and thought about what I should answer them. Was it perhaps a test question? Or was the question meant to provoke me? After all, I had criticized various engineering solutions. Could this question be serious? There were so many different levels to consider in developing actions on climate change. First and foremost was our understanding of climate change, of nature, of the survival of human civilization, followed by hypercomplex causal chains that constantly unfold as climate conditions change: Extinction of species, change of soils, loss of livelihoods.... I decided to put aside my fear and also my indignation and give a transformative response. I replied: “No, unfortunately, I must admit that I do not have a solution. It's even worse, I do not think there is ONE solution. Rather, I think there are many solutions and we must find them together. But, unfortunately, at the moment it doesn't look like all the energy is being put into finding solutions”.

Following on from this anecdote, I would like to emphasize that my teaching practice in Engineering Education has shown that it is essential for engineers to gain a more complex image of the world. That means, that, besides the social and ethical dimensions of technological issues, engineers that are concerned with sustainability need knowledge about *naturecultures*. Donna Haraway, a feminist scholar and philosopher, coined *naturecultures* to refer to the interconnectedness and interdependence of humans and the nonhuman world (Haraway 2016). Usually, "nature" refers to the nonhuman world and "culture" refers to human society. By using the term *naturecultures*, Haraway overcomes this separation and points out that humans are shaped by and are an integral part of the natural world, which is also influenced by human activities and culture. This perspective makes it possible to consider the significant impacts of human activity on the natural world, including pollution, habitat destruction, and climate change. Furthermore, and this seems to be crucial especially for the Engineering Education, a broader perspective on the relationship between humans and the environment can be developed following the epistemological concept *naturecultures*, which goes beyond the idea of nature as a resource to be exploited for the benefit of humans.

Engineers are problem solvers, and that is an important quality. It seems to give them the confidence to see problems as solvable and to approach them with the energy they need. However, as a social scientist, I also see a drawback in reducing the complexity and multi-faceted nature of the world to manageability for engineers. With such an approach, solutions can be found, but these solutions often do not fit the problems posed.

3.2 Understanding Climate Change as a Dealing with "Situatedness"

Feminist epistemology, namely Donna Haraway and Sandra Harding, have drawn attention to the fact that knowledge is always situated (Haraway 1988; Harding 1991). Knowledge, according to this understanding, is shaped and influenced by the specific circumstances and environment in which it is produced or used. The epistemological concept of situated knowledges thus makes it possible to incorporate into the research process the importance of the social, cultural, historical, and political factors that shape knowledge production and use. The advantage of this concept is that it recognizes that knowledge is not created in a vacuum, but is always embedded in powerful structures. Knowledge is also influenced by the unique situations, experiences, and agency of the individuals or communities involved.This perspective, which does not discount the importance of understanding the social and cultural context in which knowledge is created and applied, recognizes that different perspectives and experiences can lead to different forms of knowledge. By understanding that knowledge is situated, students can develop a more realistic understanding the complexity of the world and work toward more inclusive and equitable ways of producing and applying knowledge. This insight, I argue, is central not only to feminist or social science research, but also to more sustainable scientific and technological research.

In my teaching practice, I therefore attach great importance to critically reflecting with the students on the epistemological foundations on which the research is based (Trojer, 2014). In doing so, I want them to understand that developing sustainable solutions is not about developing something particularly technically innovative or sophisticated, but rather about understanding the situatedness of the technical solution as much as possible in order to be able to take this into account when developing possible solutions. In addition to reflecting on the epistemological foundations on which research is based, it is helpful for students to gain insights into more-than-technologically oriented perspectives on climate change problems, or perspectives that address social-cultural aspects in addition to technological ones. Ideally, these are studies critical of power and domination that reveal the intertwining of technological artifacts with the situatedness of individuals and social norms and discourses.

3.3 Critical Reflection – Engineers' tool for Sustainability

When we think of engineers, we usually imagine them designing artifacts on computers, building something, screwing on devices. Perhaps they also program machines or manufacture innovative parts. But what if we added critical reflection as a tool to the engineers' toolbox? I argue that critical reflection on practices of power and domination is central to engineers who want to develop sustainable technologies. My teaching practice made clear, that sustainability has to be understood less as a learning object than as an epistemological perspective. According to that, thinking about sustainability requires the ability to critically reflect on debates, discourses, and paradigms about nature, culture, and technology. This presupposes a discursive understanding of reality, a critical understanding of sociality in terms of power and domination, and a co-constitutive understanding of *naturecultures*. As I have made clear elsewhere (Dornick 2021), learning critical reflexivity is an uncomfortable and difficult process. Moreover, learning critical reflexivity requires engaged learning (hooks 1984). Students must learn to raise questions. This means not only that debates, discourses, and paradigms become in some way foreign to them, but also - especially when it comes to questioning identity categories, such as gender, class, *race* - that students become unsettled. To teach unsettling topics requires a safe and trustworthy learning environment that allows students to activate and practice "free speech, dissent, and pluralistic opinions" (hooks 2010:16), that also considers learning as an embodied process (Thompson 2017). It requires a trusting "interactive relationship between student and teacher and needs a trusting "interactive relationship between student and teacher" (hooks 2010: 19), that motivates intrinsic experimental learning. A good culture of error is essential, as critical reflection leads to uncharted territory. An indispensable factor for this form of learning is time. Students need time to understand and transfer what they have learned to their discipline. As Spelt et al. (2009) point out: “Interdisciplinary thinking does not occur spontaneously, it can take a considerable amount of time for students to achieve an adequate level of expertise in its practice.” It is therefore imperative that the learning process be designed in such a way that students are given time to converse with each other, to communicate in a trusting manner. Only in this way can transfer-knowledge emerge.

4 SUMMARY

The issues of climate change and sustainability are urgent and critical concerns of our time. Engineers play a central role in addressing and adapting to climate change. However, the problem is complex, and the sociocultural consequences of engineering actions are difficult to predict. Therefore, I focused my paper on the content and pedagogical approaches that can be used to convey the complexity of the issue while encouraging the development of critically reflective knowledge. I have argued that it is important for engineers to form a more complex picture of the world. That is, engineers studying sustainability need knowledge of *naturalcultures* in addition to the social and ethical dimensions of technological issues. Besides, students need to knowledge about the epistemological and power-laden foundations of research and the situated nature of the issues. It is important that students gain insight into non-technologically oriented perspectives on climate change issues. Most importantly, it is essential to convey that sustainability is not so much an object of learning as an epistemological perspective and that the ability to critically reflect on technology is therefore critical.

ABSTRACT

This practice paper is a descriptive account of an experience with a sustainable development learning project for engineering students in a Science, Technology and Society (STS) course at Bilkent University. The students participated in the STS Sustainability Awards competition for two semesters in one academic year, an event that was inspired by Bilkent University's 2021–2022 Sustainability Year. As part of the project, the students found a company or laboratory, consulted them on their innovation practices and asked questions that were grounded in Responsible Research and Innovation (RRI) approaches. RRI can provide an opening for students to explore how various values, including sustainability and privacy, are considered in innovation practices. The values by design approach can help engineering students to see that innovators consider both instrumental and qualitative values during the innovation process. Although the project has been used in other years, the sustainability awards motivated students to explore how innovators respond to concerns around a range of sustainability issues. The award recipients produced projects on smart homes, nanotechnology-based solar panels, clean meat, industry 4.0, geothermal energy, air cars and magnetic resonance imaging technology, and gave presentations in events hosted by the Faculty of

Engineering administrators. Although future research in this area is needed, applied learning experiences, such as the one that is described in this paper, could have the potential to help bridge the disciplinary divide between STS and engineering.

1 INTRODUCTION

1.1 Crossing the Disciplinary Divide

Although engineering students are required to take Science Technology and Society (STS) classes or other classes focused on social, ethical and environmental contexts, they are not always sure why these subjects are part of the curriculum. Engineering students do not always appreciate the practical value of applying social knowledge or ethical approaches. Newberry suggests that students often perceive learning about ethics to be a trivial and useless pursuit, partly because they do not generally see their engineering professors respond to ethical issues (2004, 347). This may be part of the reason that engineering students view societal concerns as “strictly ornamental” (Newberry 2004, 350). Likewise, Cech suggests that although engineering students often start out with a desire to solve societal problems or grand challenges, they typically concentrate on math and science during their first two years of training and this focus may take them away from the societal context culminating in the “culture of disengagement” (2014).

The apparent disconnection between social and technical knowledge among engineering students is an issue that could be addressed through applied projects and the inclusion of social values in engineering classes. It may be helpful for engineering students to receive approval from technical professors for the work that they do on social and environmental projects. Foley and Gibbs suggest that in order for engineering students to take the ethical dimensions of engineering seriously, their efforts in this area must be acknowledged by instructors and institutional administrators (2019, 13). For these reasons, it is important to introduce students to social and ethical issues that come up in the innovation process in a way that allows them to receive recognition for their work on sustainability practices from the engineering faculty in which they are trained. It is also essential to encourage students to engage with innovators, so that they can see how social and environmental values are managed in an applied context.

1.2 Applied STS Projects at Bilkent University

The STS course at Bilkent University is supported by the Faculty of Engineering. It has been managed by the Faculty of Engineering for over twenty years and was originally introduced by Haldun Ozaktas, a Professor in the Department of Electrical and Electronics Engineering (Ozaktas 2013). The main role of the 2-credit course is to respond to Accreditation Board of Engineering and Technology (ABET) goals through addressing social, ethical and environmental values. The course is currently taught by instructors with expertise in Science and Technology Studies and we ask students to engage with innovators for their term projects. Students can use different theoretical approaches, including responsible innovation, social construction of technology and actor network theory. The students typically use interviews to consult the innovators on their innovation practices, but they can also use field notes or website scans.

The STS Sustainability awards competitions were introduced in 2021 and 2022 as part of a larger institutional sustainability initiative (Bilkent University n.d.). The sustainability awards motivated students to explore how innovators respond to concerns around a range of sustainability issues using a responsible research and innovation (RRI) approach. The students identified an innovation site and conducted interviews with engineers at the site. The jury came from several different departments, including urban design, industrial engineering, education and electrical engineering. The jury awarded STS Sustainability Awards to projects that were clearly focused on sustainability, including clean meat, geothermal energy and nanotechnology-based solar panels. They also gave awards to projects that discovered sustainability practices or envisioned future sustainable technologies in the area of smart homes, industry 4.0, air cars and magnetic resonance imaging (MRI) technology. The STS Awards provided an opportunity to showcase STS student work in a formal auditorium setting. The events were hosted by the Faculty of Engineering administrators (Science Technology and Society n.d.). Through conducting RRI studies, the students discovered how a range of values, including sustainability, may be included at an early stage in the innovation process.

2 ENGAGING ENGINEERING STUDENTS IN SOCIAL AND ENVIRONMENTAL ISSUES WITH RESPONSIBLE INNOVATION

2.1 RRI: Beyond Corporate Responsibility

Responsible Research and Innovation (RRI) approaches provide an opening for students to explore how various values are considered in innovation practices. The values by design approach can help engineering students to understand that both instrumental and qualitative values can be included during the innovation process (van de Poel 2015). The social values may include gender inclusion, stakeholder concerns, user experience, privacy and environmental aspects. One of most cited RRI definitions demonstrates that the approach incorporates both economic and social contexts, in addition to tangible outcomes:

> Responsible innovation is a transparent, interactive process by which societal actors and innovators become mutually responsive to each other regarding the ethical acceptability, sustainability and social desirability of the innovation process and its marketable products. (Von Schomberg 2013, 63).

RRI has also caught the attention of industry, which is an indication that it can be useful in an applied context and, for this reason, should be of interest to engineering students (EIRMA n.d.). For example, several Horizon 2020 projects focused on how to assess RRI in industry (van de Poel et al. 2020; Responsible-Industry n.d.). This practical dimension also has applications in engineering education. For example, RRI approaches can be helpful for problem-based learning, partly because it provides a lens for examining responsiveness and solutions (Conley, Tabas and York, 2022; Stilgoe, Owen and McNaughten, 2013).

Sustainable development and responsible innovation intersect in many ways and provide methods and opportunities for both engineering educators and industrial actors to include social and environmental values. As a concept, sustainability has been embraced by industry and environmentalists, even though these stakeholders often have different understandings of the term (Robinson, 2004). However, these differences provide flexible opportunities for the inclusion of various values. The Brundtland report called for sustainability assessment tools to be further developed at an early stage, but they remain notoriously difficult to implement: "[T]he tools for monitoring and evaluating sustainable development are rudimentary and require further refinement" (Brundtland 1987, 256). Indeed, corporate strategies have not always developed in complete alignment with the Brundtland report (Barkemeyer et. al. 2014. 28). Although innovators have had corporate social responsibility (CSR) strategies in their company objectives for some time, it is difficult to standardize measurements (van Marrewijk, 2003; Contrafatto and Burns, 2013, 359). Much like sustainability, responsible innovation is a flexible concept that includes a focus on economic aspects, innovation and social and environmental issues (Guston, 2015). Given that views and definitions for sustainable development and responsible innovations can vary, it may be helpful to use qualitative approaches as assessment tools, mainly because they offer more versatility and can also be used to promote better practices.

Some scholars have been investigating the relevance of RRI for industry, which is clearly significant for future engineers. Developments in RRI that use qualitative assessments may be more appropriate for discovering concrete results and sustainability practices. For example, PRISMA is an RRI project that investigates company practices. The project used a bottom up approach to RRI investigations and recognizes that companies are already engaging in some responsible practices. For example, some companies have CSR practices in place and they also pay attention to conflicts between values. The PRISMA researchers have found, for example, that profit sometimes supersedes stakeholder interests and transparency (van de Poel et al. 2020, 699). They also suggest that companies can improve RRI practices through the following methods: "strategize for stakeholder engagement", "broaden current assessments", "place values at center stage", "experiment for responsiveness", "monitor RRI progress" and "aim for shared value" (van de Poel et al. 2020). The responsiveness element goes beyond merely discovering values to realizing outcomes. In this way, RRI goes beyond CSR assessments. By suggesting that companies experiment for responsiveness, they also draw attention to the technical creativity that is needed to discover potential solutions to social and environmental risks. This is also a key part of the exercise for the STS students.

2.2 Applied RRI for Engineering Students

The applied projects have created a new opportunity for educating STS engineers in responsible innovation theories and methods. In a group context, students identify a company or a lab and conduct research through interviews or ethnographic approaches. Students are asked to engage in an investigation of one field site (a lab or a company), reflect on a range of values in the innovation process and consider some of the trade-offs that are made by engineers and scientists in a real-world setting. Students examine the role of users and stakeholders, investigate relevant policy developments, identify potential risk issues and, if relevant, discover responsible solutions. The groups choose a variety of sites, including, for example, social media companies, energy companies, simulation research centres, medical imaging projects, nanotechnology labs, cyber security companies, factories, alternative meat production and artificial intelligence applications.

Through the analysis, the students uncover various aspects of RRI that are important to their sites of analysis. These include collaborations with different stakeholders or academics from different disciplines, the inclusion of user experience in innovation, attention to privacy by design practices and the identification of possible solutions to social concerns. Students are able to assess key risks and benefits, which may generally arise in the specific research and innovation context where they are conducting their interviews. The initial desk research that students conduct enables the students to ask representatives from labs and companies pertinent questions about their innovation practices. Students often find that researchers have considered social and ethical values during the innovation process. In some cases, their research findings demonstrate that innovators respond to these risks with technical adjustments or they make changes to the practices or policies associated with the technical development. This can be surprising for some students, as this part of the innovation process is not typically highlighted in their engineering classes. If students find examples of technological adjustments that respond directly to social or environmental concerns, such as privacy-respecting mechanisms or sustainability measures, in their background research, then they are in a position to make suggestions for how the company or lab can address risk issues in the analysis section of their term project.

3 STS SUSTAINABILITY AWARDS

3.1 Method and General Outcomes

As a part of the 2021 and 2022 sustainability awards competitions, students were asked to use a responsible innovation approach and place an emphasis on sustainability. The students recruited companies and research sites, conducted their interviews, analyzed their interview transcripts and finalized their reports. The students reported on all of the values that they found through their research and highlighted values related to sustainability. Some students found that engineers considered sustainability solutions. Students also learned that innovators encountered value conflicts in their attempts to find sustainable solutions. The Faculty of Engineering administration supported the event through making and giving out certificates and listening to student presentations. Their participation helped to give the event prestige, which may have also helped to motivate the engineering students.

At the end of the Fall 2021 and Winter 2022 terms, the jury reviewed projects and considered them for the STS Sustainability awards. In the Fall semester, ten projects were sent to the jury from twelve STS sections (about 240 students) and they gave awards to five projects. In the Winter semester, the jury awarded three projects from six sections (about 120 students). The jury assessed the projects according to a focus on sustainability (40 marks), attention to key stakeholders (10 marks), the inclusion of relevant risk issues (10 marks), attention to solutions to risk issues and stakeholder concerns (10 marks), originality and creativity (20 marks) and writing (10 marks). The award categories varied in each semester, but included Outstanding STS Sustainability Award, Sustainability and Innovation Award, Social Justice and

Sustainability Award, Energy Futures and Sustainability Award and the Sustainability and Equity Award. Seven of the projects that received awards agreed to post their projects on the STS website after receiving permission from the companies that participated in their studies. I will provide some general examples of findings from their reports related to sustainability below (Science Technology and Society n.d).

Table 1. Sustainability Findings in Student Projects

Types of sustainability findings in student projects	Projects
Projects focused on sustainability technologies	• Cultured Meat: Meet the New Meat (Outstanding STS Sustainability Award 2021) • Sustainability Analysis of Turkey's Leading Geothermal Energy Company Based on Responsible Research and Innovation Theory (Energy Futures and Sustainability Award 2021**)** • Graphene-Based Solar Cells in the context of Responsible Research and Innovation (Outstanding STS Sustainability Award 2022)
Projects that found value conflicts related to sustainability	• Graphene-Based Solar Cells in the context of Responsible Research and Innovation (Outstanding STS Sustainability Award 2022)
Projects that discovered examples of the inclusion of sustainability adjustments to the technology	• Graphene-Based Solar Cells in the context of Responsible Research and Innovation (Outstanding STS Sustainability Award 2022) • Tangible Social Concerns in a Digitalized World: An RRI Case Study on Digital Transformation Technologies at TEKNOPAR **(**Sustainability and Equity Award 2022) • A Case Study on Karel Electronics Smart Home Technology Through the Lens of Responsible Innovation (Social Justice and Sustainability Award 2021)
Projects that identified sustainable practices	• AirCar: A "Jetsons" Dream Coming True (Sustainability and Innovation Award 2022)
Projects that included a vision for a future sustainable technology	• AirCar: A "Jetsons" Dream Coming True (Sustainability and Innovation Award 2022**)** • Responsible MRI: RMRI (Sustainability and Innovation Award 2021)

There were a few examples of companies that were working towards sustainable development goals, but award recipients also found examples of sustainability practices in other sectors (see Table 1; Science Technology and Society n.d.). For example, the geothermal project and the clean meat projects found that sustainability was a key goal for the companies that they consulted, so they were clearly building environmental values into their technology. The geothermal project noted that the company wanted to be the energy company of the future for Turkey and envisioned a future that would us mainly renewable sources. Students found that Biftek emphasized how conventional meat is not a sustainable option and a transition to clean meat would help to solve this problem. While Graphene-Based Solar Cells is obviously focused on developing sustainable technology, students also discovered that researcher and engineers sometimes encountered conflicts between different types of values. For instance, through their interviews, students found that it is economically more viable to work with heavy metals, but they chose to use boron instead as it is a more sustainable option. The students pointed out that the innovators made this decision because they were concerned about environmental values. Other groups found that their interviews had made technical adjustments to improve sustainability. For example, TEKNOPAR used sensors that would keep track of electricity use and potentially reduce greenhouse gas emissions. Similarly, Karel had implemented smart plugs and lighting for the same purpose. The interviewees from the AirCar company indicated to students that their future technology would not actually be owned by individuals. Rather, they envisioned that future air cars would be shared by users, which is similar to sustainable car sharing practices that are already in place. Students also found that some of the sustainable technologies that were discussed by the innovators are still at the aspirational stage. However, although the AirCar technology is still in development, the engineers were already working towards significantly reducing emissions. Finally, the MRI group noted that the future development of smaller MRIs would make the technology more sustainable.

4 SUMMARY AND ACKNOWLEDGMENTS

4.1 Summary

The STS Sustainability Awards were an opportunity for engineering students to learn about sustainability issues, examine the unintended risks and identify possible solutions by using responsible research and innovation approaches. The students discovered industry-based sustainability practices through their efforts. It is possible that students may have a better understanding of the relevance of social and environmental values through conducting their investigations, but this would need further research. As noted above, engineering students do not always view courses that focus on social knowledge as relevant to their future technical careers. This learning activity addressed this problem in two ways. Firstly, by consulting innovators on the values that are included in the innovation process, students had an opportunity to realize that social values, including sustainability, are routinely considered by researchers and real-world developers. Secondly, perhaps by including participation from engineering faculty in STS course activities, it may have helped to validate the time that engineering students spent on the responsible innovation inquiries. However, these issues would need to be explored further by future researchers, as this paper only describes the project, the competitions and some of the key findings from student projects. Of course, there are ways that the project can be improved, if implemented again in the future. Although it is useful for students to find a company that is actively working on sustainable technologies, it is also important to discover the conflicts, risks or unanticipated consequences associated with the sustainable innovation that they are examining. This aspect does not always receive as much attention. Also, it is important to stay open to sustainable innovation practices in all sectors, rather than only investigating innovations that are exclusively focused on sustainability. Students were asked to imagine solutions for sustainability dilemmas, particularly if the innovators that they interviewed did not mention one, but this was not always successfully addressed. This dimension could be developed much further, although students may not have always have time to identify appropriate solutions. Overall, the sustainability competition was a successful initiative, as it helped students to reflect on sustainability in innovation practices. The STS Sustainability Awards also provided a useful way to draw attention to STS student work on sustainability, as representatives from the Faculty of Engineering attended the events, presented certificates to award winners and heard the students give talks on their projects.

4.2 Acknowledgments

I would like to thank two anonymous reviewers for their valuable comments. The SEFI 2023 conference organizers were also incredibly helpful guides throughout the review process. I would also like to thank Dr. Ezhan Karaşan for his support and guidance while he was the Dean of the Faculty of Engineering at Bilkent University. Dr. Nail Akar, the Associate Dean of the Faculty of Engineering, also supported this effort. I gratefully acknowledge Dr. Didem Dizdaroğlu, Dr. Jennie Lane, Dr. Selin Kocaman and Dr. Haldun Özaktaş for acting as jurors for the STS Sustainability Awards. Dr. Jeremy Hall, Dr. Zeynep Yöntem and Mete İmer supported the events with talks on sustainability and engineering. Dr. Emine Öncüler Yayalar contributed to the organization and development of the 2021 event. Finally, I sincerely appreciate the efforts of the STS Sustainability Award recipients. Their final projects can be found on the course website (Science Technology and Society n.d.).

ABSTRACT

This study explores the influence of an interdisciplinary intervention on creative problem-solving skills. Literature deems such skills as vital for software engineering (SE) students in higher education. 39 SE students and graphic design (GD) students were randomly paired to work on an open-ended creative coding assignment in p5.js, an online JS-based Processing editor that makes it easy for novices to quickly and easily code visual webpages. Three categories were formed: the test group SE+GD (18 students), and control groups SE+SE (10) and GD+GD (11).

[1] *Corresponding Author, K. Aerts,*

kris.aerts@kuleuven.be

A mixed methods approach was taken to gather and interpret results: Amabile's Consensual Assessment Technique provided a global creativity score for the finished product, the Creative Programming Problem Solving Test assessed three dimensions of the creative process (*Ability, Mindset, Interaction)*, and 9 semi-structured follow-up interviews provided context and revealed underlying themes. The results indicate that, while the creativity of the end product initially takes a hit, the SE+GD groups' socio-interactive creativity levels increased. We also observed fixed mindsets towards creativity ("design students are more creative than we") that call for future work.

1 INTRODUCTION

Many studies emphasize creativity as an essential problem-solving skill in the world of computing (Apiola and Sutinen 2020; Salgian et al. 2013). A recent Delphi study reveals: SE industry experts rate creativity as crucial to succeed as a developer (Groeneveld et al. 2020). Another study concluded that in order to foster creativity in higher education, three approaches can be taken (Groeneveld, Becker, and Vennekens 2021):

- Introduce experimental learning. Experiments with open-ended project-based learning have been shown to be beneficial towards students' creativity.
- Get students out of the classroom. The environment in which the learning takes place plays a significant part in the creative potential of students.
- Put creativity first, programming second. This opens up computing to a more diverse student population.

This paper provides an experience report that combines all three approaches and adds upon it by introducing an interdisciplinary approach for developing SE student's creative skills. In our approach SE students are paired with GD students in an experimental open-ended learning project using creative coding in the programming framework p5.js. The project took place in the design classrooms of another university. And lastly, we put creativity first by refraining from grading and emphasizing on experimentation and having fun as a goal in itself.

The goal was to amplify creative problem-solving capabilities of SE students in higher education, beyond the conventional approaches. Since creativity can express itself in different ways, we ask the following questions:

- **RQ1**: *What is the influence of an interdisciplinary creative coding project on the creativity of the* ***process****?*
- **RQ2**: *What is the influence of an interdisciplinary creative coding project on the creativity of the* ***end product****?*

The remainder of this paper is structured as follows. Section 2 outlines related work, Section 3 describes the mixed methods approach utilized to gather results. Those results are presented and discussed at length in Section 4. Next, in Section 5, we highlight possible limitations of this work. Finally, Section 6 concludes this research and suggests future work.

2 BACKGROUND

2.1 Interdisciplinary collaboration

In the paper “Ten Cheers for Interdisciplinarity” (Nissani 1997) creativity is considered one of the reasons to pursue interdisciplinary collaborations. "Interdisciplinary computing classes are worth the effort", concludes Lori Carter (Carter 2014). We believe this to be especially relevant in the field of computing where the demand for interdisciplinary skill crossovers is growing, according to (Carr, Jones, and Wei 2020).

2.2 Creative coding

The concept "creative coding" is often employed in curricula to explore code as a medium for self-expression (Peppler and Kafai 2009). The focus here is not sparking creativity to deal with daily programming problems, but rather to use code to express your creative urge. This is typically done using the Processing (p5.js) programming language and has been known to increase engagement and excitement for computing (Greenberg, Xu, and Kumar 2013). The focus on visual creations entices students, while at the same time offering a decent programming challenge.

2.3 Creativity and how to assess it

Creativity is a broad concept that, even when viewed from a computational perspective, seems to codify multiple perspectives: creativity by yourself, in teams, or on socio-organizational levels (Veale, Gervás, and Pease 2006). Precisely because of ongoing discussions whether or not the concept of creativity is context-dependent (Baer 2010) and disagreements on numerous definitions of creativity (Groeneveld, Becker, and Vennekens 2021), a plethora of assessment techniques have been published. Yet many existing assessment tools, including those from the field of cognitive psychology, fall short of measuring multiple dimensions of creativity. For instance, the well-known Torrance Test of Creative Thinking (Torrance 1972) gauges divergent thinking but ignores creative collaborative aspects. Personality-based self-tests such as The Big Five emphasize individual creativity and motivation (Sung and Choi 2009). Amabile's Consensual Assessment Technique (CAT) employs a jury to score the creative output but ignores the creative process (Amabile 1982). Recently, a new creativity self-assessment tool was developed specifically geared towards problem solving for computing students, called the Creative Programming Problem Solving Test (CPPST) (Groeneveld et al. 2022). It contains three overarching constructs of creativity based on existing validated scales and conducted focus groups: *Ability* (knowledge of coding and creative techniques), *Mindset* (curiosity and belief in own abilities), and *Interaction* (social aspects of creativity).

3 METHODOLOGY

Before elaborating on the data gathering processes, to help the reader interpret the results, we first describe the target groups involved in this study.

3.1 The Setting

Students from two entirely different programs took part in the experiment: 19 second-year students from our local faculty of engineering technology electronics/ICT and informatics (SE) and 20 students from the faculty of visual design from a neighboring university (GD). As creative skills are a learning outcome for both groups of students, all students were expected to participate, but to avoid pressure no grades were attached to the process nor to the results. Students could also bail out of filling out any form or participating in the interviews without any consequences, resulting in a setup following the guidelines of the Privacy and Ethics Unit of the university.

All participants were randomly placed into one of three groups: The test group SE+GD (18 students, 9 duos), the control group SE+SE (10 students, 5 duos) or the control group GD+GD (11 students, 4 duos and 1 trio). None of the students had prior experience with the p5.js framework. So an introduction session of two hours was given to all participants. In this study, the decision to use Processing was not made to explore creativity as a means for self-expression like in (Peppler and Kafai 2009), but as a means for problem solving. To minimize unwanted side effects during measurements, all groups were placed in the same physical location, including control groups SE+SE and GD+GD. We chose the buildings of the design faculty for the location since we were most interested in the possible deltas of SE students and, as explained before, wanted to "get students out of the classroom". Of course, for the design students, the location didn't change. As for the project assignment itself, it was delineated, but not too much, as to leave room for creative freedom. The pairs had to create a visual exposition that emphasizes user interaction, for instance through sound, camera, or mouse input. The assignment had to be completed on a single day. All projects were incorporated into an online p5.js exposition.

3.2 Measuring The End Result: CAT

Well beyond the field of cognitive psychology, Amabile's CAT is commonly used to evaluate the creativity of an end product (Baer and McKool 2009), in our case, each p5.js project. CAT relies on expert judges that score the creativity of an end product between 1 and 10. Since the scoring process is very subjective, it is recommended to recruit multiple judges and work with an average. For this study, we enlisted seven judges that are part of the teaching staff of the involved courses: three computing experts (all co-authors), and four GD experts, of which two eventually opted out of the study. The judges were instructed in individually evaluating the creativity of each anonymized project by spending exactly one minute on each project. We refrained from providing a definition of creativity, as per recommendation in (Baer and McKool 2009). The standard deviation (SD) of the scores, on average 1.44, mirrored Baer and McKool's conclusion: judges score surprisingly similar (Baer and McKool 2009).Therefore, for CAT, inter-rater reliabilities are not relevant. However, as an extra verification step, when judges did not agree (threshold of $SD > 1.80$, 5 out of 19 or 26% of the projects), those projects were re-discussed in group, after which new scores were assigned and an SD calculated, until the threshold was reached.

3.3 Measuring The End Result: CPPST

Next to evaluating the end result with CAT, we were also interested in different aspects of the creative process. The CPPST tool allows us to assess whether or not our interdisciplinary intervention has effect on specific parts of students' creative problem solving abilities. The CPPST is a self-assessment test which was administered at the end of the project day. In it, students answer 56 questions on a Likert-5 scale. The full question set is available in (Groeneveld et al. 2022). A reduced set of 32 questions are enough to gauge the three factors of the CPPST, but we opted to include the full set as the extra data might help us in asking more specific questions in the semi-structured interviews.

3.4 Enriching quantitative data: interviews

The different CAT and CPPST values are devoid of rich contextual information. Therefore, we decided to conduct additional interviews to put these numbers into context based on the results of the aforementioned tests. After the CPPST survey results were collected, average and SD values were calculated for each question, grouped by the three student categories. Next, since we were most interested in the impact of the interdisciplinary component, deltas (δ) of averages between the subgroup SE from SE+GD vs SE+SE and the subgroup GD from SE+GD vs GD+GD were calculated. A $\delta > 0.5$ was marked as potentially interesting. Hove and Anda's recommendations for conducting semi-structured interviews in empirical SE research (Hove and Anda 2005) combined with a discussion of the deviating δ values of the CPPST results guided us to the following question sets, divided into two distinct themes: **general context** (1-2) and more **in-depth**-related (3-9) questions:

1) What did you think of the experience?
2) How did the collaboration go?
3) How did you tackle the project in general?
4) How did you tackle brainstorming and ideation?
5) What did you do when a problem occurred and you were stuck?
6) What did you learn with this project?
7) In which way did you get out of your comfort zone?
8) How did you tackle the openness of the assignment?
9) What would you do different if you were to re-do it?

Our aim was to interview a random selection of 30% of the participants of each group. Data from the interviews was processed using qualitative coding as presented by Onwuegbuzie et al. (Onwuegbuzie et al. 2009). The transcripts were read multiple times independently by two co-authors to apply an open coding step, initially identifying 43 codes. Next, in order to identify patterns, notes were compared, cross-validated, and reduced into 25 codes grouped into 4 themes in an axial coding step. These themes served as a starting point for discussion and to cross-link back to the quantitative results. The resulting themes and codes are presented in section 4.

4 RESULTS AND DISCUSSION

At the end of the project day, all pairs successfully created an interactive visual exposition. An overview of the projects, together with all open data used in this study, is available at https://arneduyver.github.io/creative-coding/gallery. Some examples:

- Abstract art that reacts to sound or mouse input.
- "Draw in the air" using the camera.
- A text to music generator.

4.1 Quantitative results

The CAT scores of the SE+GD, SE+SE and GD+GD groups were respectively 6.30, 6.88 and 6.04. Although these differences can be considered small, it is interesting to note that the test group of interdisciplinary teams (SE+GD) scored with 6.30 less than the pure SE teams (6.88). To verify if the differences originate from the creative process, we took a closer look at the CPPST measurements (on a scale of 5).

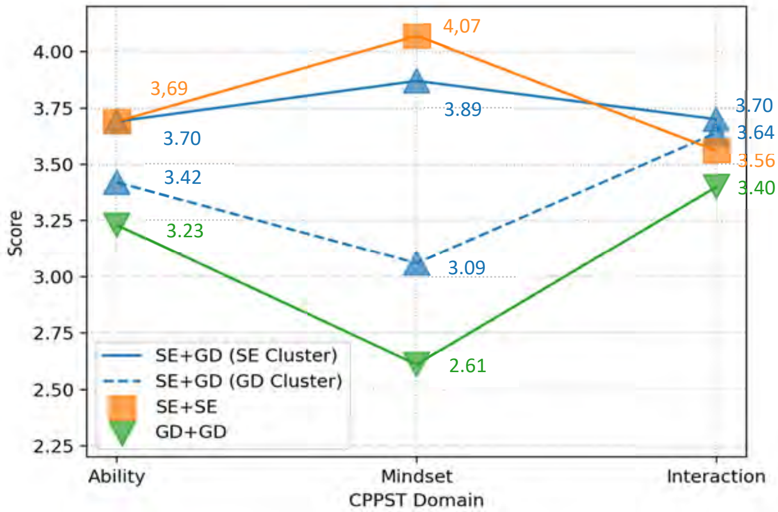

Figure 1: Average CPPST domains for groups SE+GD (△), SE+SE (□), GD+GD (▽).

Figure 1 shows that the interdisciplinary test group performed marginally better at *Interaction* level, and especially in the socio-interactive components of creativity, probably because their different backgrounds enforce more discussion. However, the biggest gap is in *Mindset* with low scores for for the GD+GD group, but also for the SE+GD groups with a GD majority. It might be that they struggled with the complexity of programming and had no access to a SE student to solve this, or it might be a sign of a fixed mindset (“I can’t code”) that resulted in an early defeat. As CAT and CPPST are devoid of context, a qualitative interpretation is needed.

4.2 Qualitative results

In total, 9 students were interviewed: 5 from the SE+GD group (3 from SE and 2 from GD, thus 29.4% of that population), 3 from the SE+SE group (33.3%), and 1 from the GD+GD group (9%). Since we are mostly interested in the effects of the intervention on the SE students, we do not consider the small GD sample size as a threat to the validity of the study. Transcript analysis initially yielded 43 codes across all groups, reduced to 25 and categorized in 4 distinct themes: *Curiosity* (6), *Cooperation* (7), *Method* (7), and *Mindset* (5). We now briefly describe findings of each of the themes with codes emphasized in bold.

CURIOSITY - Almost all interviewees appreciated the opportunity given to **explore beyond their education**. SE students mentioned they "*had no idea it was that easy to create something visually*". Especially **being in the same space** turned out to be inspirational, as students regularly got up to see others at work and mentioned ideas cross-pollinated quicker that way. The unique **physical environment**, as per recommendation in (Groeneveld, Becker, and Vennekens 2021), seemed to inspire SE students:

> *I was very impressed because as you entered, there were drawing tablets, 3D printers, a green room for photography, ...Then more ideas will come to you.*

Another trigger for curiosity was p5.js itself, as the **framework facilitated play**: students praised the clarity of the documentation and the easy-to-use web editor that facilitates experimentation through rapid feedback. The **freedom** and absence of the stress in anticipation of a grade was also reported to play a role. The interviews also revealed that **frustration** was a big factor limiting creativity.

COOPERATION - SE+SE students working in a homogeneous group mentioned cooperation was **smooth**, even if they did not know their partner. Yet, for the heterogeneous SE+GD group, collaborating was **very difficult**. "*Working together with a complete stranger was hard.*" When asked why, several reasons were given: (1) It was "*difficult to explain your own way of thinking*"; (2) "*I really had to drag it all out [of my partner]*". (3) Some students wanted to get to know their partner, while others wanted to start coding immediately. The different fields of study might also imply a difference in personality and approach. **Giving feedback** proved to be a challenge as well. The interviews confirm that the social aspects of co-creating was what pushed students **out of their comfort zone**. Some homogeneous interviewees realized that cooperating--and possibly, the creative outcome--would be **very different in a mixed group**, but in a good way: "*I found projects from the mixed group to be excelling [...] they had ideas that were more interesting than ours*". Although "*more interesting*" did not result in higher average CAT scores, all students do **acknowledge that cooperation is an important factor** to creative success.

METHOD - SE+SE and GD+GD groups applied **different approaches**. The former look at examples, think about what they like to do based on the examples, and immediately start exploring that in code, while the latter first brainstorm for ideas, sometimes **iterating** over them, and only then look at what is possible to try and implement their ideas. SE students mentioned they had **difficulties with the openness of the assignment**. Some SE+SE students admitted spending too much time trying to come up with a concept, struggling with what they wanted to create. For SE+GD groups, there was a **stereotypical task division**: "you *do the code, I'll do the design*". As to what to do when stuck, SE+GD students mentioned they liked to "***get up and walk around*** *[...] I take that as a moment to think about something else [...] and usually come back with a solution*". SE+SE students prefer **diving into the docs** before asking for help.

MINDSET - Interviews revealed many **prejudices**: from "*creating something visual is hard*" (SE) to "*I can't code*" (GD). As much as everyone acknowledged **importance of heterogeneity in teams** and lauded the experiment as **refreshing**, we discovered a **fixed mindset** when it comes to creativity. SE students say "*design students go more in the creative direction while we use logical steps to solve things*", while GD students say "*coding is very mathematical*" and imply it is less creative than their visual work. Clearly, this fixed mindset can be very damaging to the creative potential of SE students. Also, students have a **wrong image** of what an engineer or designer does, as a GD student testified:

> *I think we're more the people who ask questions while you just tell an engineer to do this or that and he'll understand it that way.*

5 LIMITATIONS

This paper reports on an intervention with a relatively small group ($n = 39$). Although judging from the recurring themes throughout the interviews, we believe that the findings of this paper will persist. Since the cooperation between different student groups caused friction, a prolonged intervention of for instance a week could iron out the initial acquaintance difficulties. We suspect that the CPPST *Interaction* δ between the groups would even be bigger then, possibly also increasing *Ability*, but the creativity prejudices would likely remain. Future work might shed more light on this.

6 CONCLUSION

This study explored the influence of an interdisciplinary intervention on creative problem-solving skills by pairing up SE students with GD students. A mixed methods approach helped in identifying and understanding the various effects of the intervention. While we observed a slight decrease in the creativity of the end product (RQ1), the CPPST reveals that although *Mindset* needs more work, our intervention effectively increased the *Interaction* part of the creative problem-solving process (RQ2). It is important to note that due to the various reasons touched upon while discussing the qualitative results in Section 4.2, creativity can initially take a hit during interventions. This should not worry educators but is something to be aware of. Using a measurement such as CAT is not enough to reveal the underlying constructs behind the numbers. As many students testified, the intervention was a great experience to get a taste of *real* creative cooperation, even though this is not visible by looking at the CAT results. And yet, a recent literature review revealed that most computing education studies on creativity employ a single metric (Groeneveld, Becker, and Vennekens 2021). We also found the fixed mindset approach towards creativity to be very problematic, especially for the teaching staff who try to improve the creative skills of students. This has also been noted by Apiola & Sutinen (Apiola and Sutinen 2020) and Groeneveld et al. (Groeneveld et al. 2022). We have not encountered any studies that try to mitigate this. We see no easy solution and thus feel that this requires immediate attention from the computing education community.

ACKNOWLEDGEMENTS

Thanks to all students and creativity judges for their enthusiasm and interest.

ABSTRACT

The development of problem-solving skills is an important subject in engineering curricula. Helping novice students develop such skills can be challenging because problem solving is a complex skill in the sense that it is accompanied with an internal thinking process that many experts are even unaware of doing. From a combination of literature and a thinking-aloud exercise with the entire teaching team, a scheme with building blocks and strategies that are commonly used by engineers was constructed. In addition to commonly named steps such as Identify/Define, Plan/Choose, Carry Out/Do and Look back/Inspect the scheme refines the first step into multiple interdependent building blocks, emphasizes the need for critical reflection at each point as well as the possible need to return to previous steps at any time. Moreover, multiple correct solution paths can be followed in solving a problem. To address this and to empower the students in their divergent thinking processes when solving a problem, an innovative intra-exercise adaptive e-learning tool was created. The anywhere-anytime availability enables for virtual and remote learning in the post-COVID world. In the learning tool students can choose between different solution paths, after firstly identifying the correct context, parameters etc. This paper describes the process of defining the building blocks, resulting strategy scheme and implementation of the building blocks in the adaptive e-learning tool. Initial findings indicate that the strategy scheme consisting of building blocks and the adaptive e-learning tool help students in developing their problem-solving skills.

1 INTRODUCTION

As stated by Docktor et al., solving complex problems is an essential skill for all to possess (Docktor et al. 2016). This is especially true for engineers since problem solving plays an important role in their profession. Many higher education institutions therefore see it as an important task to help engineering students develop their problem-solving skills (Neri et al. 2010; Pavlasek 2014). However, Harshkamp and Suhre noticed that students are often taught to solve problems by using solution methods for a specific topic, e.g. in engineering mathematics or physics courses, and less time is devoted to teaching general problem-solving skills (Harskamp and Suhre 2007). The risk of this is that students see problem solving as performing a predefined number of steps dependent on the actual topic. Yet students are expected to solve ill-structured problems in a variety of domains once graduated (McNeill et al. 2016). Our contribution is that we have deconstructed problem-solving skills in more detail than previous work, and conveyed it to first year engineering students in a specific course on problem-solving skills. As problem solving is not a linear process and as multiple paths can lead to a solution, we have also implemented a number of online learning modules with intra-exercise adaptivity and multi-branched solution trees that support the divergent thinking of different types of students. This contrasts with existing tools that guide the student in a fixed, predefined path.

We begin this paper with a *Rationale,* based on a *Literature Overview. "A problem"* is defined and an overview is given of methods for teaching and measuring problem-solving skills, including digital and adaptive learning tools. Next, *Developing the problem-solving building blocks*, describes the process of deconstruction and the resulting problem-solving scheme consisting of building blocks and strategies commonly used by problem solvers. In *Applying the building blocks in teaching,* we show our implementation in- and outside class. *Reported Effects* discusses the findings of a questionnaire answered by 101 out of 194 students. Points of attention and continued research are the subject of *Threats to validity and Future Work. Conclusion* summarizes the main findings.

2 RATIONALE

To be able to teach problem-solving skills, we need a definition of "a problem" and "problem-solving skills". We start with the general definition of a problem (Maloney, 2011):

> *"Whenever there is a gap between where you are now and where you want to be, and you don't know how to find a way to cross that gap, you have a problem."*

This broad definition aligns well with our own idea of a problem since it makes an implicit, but important distinction between performing a task and solving a complex problem. For us, anything that can be solved by following a straightforward procedure is to be considered a task, not a problem, i.e., it is only a problem if *'<u>you</u> don't know how to <u>find a way</u>'.* A problem solver is somebody who finds such a way. In the quote we intentionally underlined not only *<u>find a way</u>*, but also *<u>you</u>*: a task for an expert can be a very big problem for a novice: because of unfamiliarity with the subject, but also because of inexperience with problem solving. Experts are not only an expert in the domain (the *what*), but are also experts in organizing their knowledge (the *how*) in order to see the core relevant principles applicable to the problem at hand, whereas the decision-making process of novices is more narrowly context related (Docktor et al. 2016; Neri et al. 2010).
The strong link with context is prominently present in most approaches to teaching problem solving skills, tying it to a concrete subject (Docktor et al. 2016; Neri et al. 2010; Harskamp and Suhre 2007). However, others put the generic skills first (Kalyuga and Sweller 2005) and stress the uncertainty in the path to the goal and the fact that making mistakes and problem solving go hand in hand (Martinez 1998). We adhere to this vision and have deconstructed problem-solving skills into a set of thought constructs that may help in paving a path, independent of the actual problem domain. We also take care of making students comfortable with the idea that reflecting often and even backtracking, is not a failure, but a very typical instrument of the expert problem solver.
Proper support is needed for the students in this potentially uncomfortable endeavor, both inside and outside class. E-learning has been used before for problem solving, e.g. in the domain of physics (Neri et al. 2010), mathematics (Harskamp and Suhre 2007; Melis et al., 2001), or STEM (Netwong 2018), and even the concept has been mentioned, e.g. "intra-exercise adaptivity" (Göller et al. 2017). "intra-exercise branching" (Mei and Heitzer 2017) and "a branching system of programmed instruction" (Lockee, Moore, and Burton 2004), but we have not found examples of explicit support for multiple solutions paths in generic problem solving with continued feedback along each path.

3 DECONSTRUCTING PROBLEM-SOLVING INTO BUILDING BLOCKS

3.1 Context

In 2018 a specific course on problem solving skills, Basic Engineering Skills (BES), was introduced in our faculty of Engineering Technology at [university omitted for anonymity]. The course is part of the general engineering phase of three semesters, after which students choose one of seven options such as Chemistry, Construction Engineering, Electromechanics, Software Systems, … and is also part of the bridging program for students who already graduated in a related bachelor's degree, e.g. in chemistry or electronics, and seek to acquire a master in engineering technology.
Focusing on problem solving and not on the underlying subject, the problem domains of the exercises were carefully selected to match the knowledge and skill set of the incoming students, who could also use a reference sheet of basic, frequently used formulas. This ought to create a common ground and align with the practice of many courses where problem-solving exercises are used to assess students' comprehension on a certain topic (Docktor et al. 2016; Neri et al. 2010). As the difficulty of the context is reduced in our approach, we hoped to be working only on the problem-solving skills. However, depending on both the background and envisioned major of the students, the perception of the exercises ranged from a (complex) task to a real problem. E.g. an exercise with a context from chemistry, would be a task for a student with a strong chemical background, at the same time posing a challenging problem for a student orientated at computer science. To overcome this, we started an educational innovation project in 2022.

3.2 The process

Because we see problem solving as a complex skill accompanied with an internal thinking process that many experts are even unaware of doing, we deemed it important to first make the unconscious problem-solving schemes and strategies explicit. The first step therefore consisted of a thinking-aloud exercise similar to a method to gauge the level of problem-solving skills of students by having them verbally explain every step in solving the problem as is described in literature (Docktor et al. 2016; Mueller et al. 2017). Each member of the BES teaching team (seven experienced lecturers from five different disciplines) was instructed to individually note every little step of their problem-solving process while solving the same problem as the other participants. Next, pairs were formed in which the approaches were discussed in depth. Finally, a group discussion took place which revealed many different paths, but also similar strategies for approaching the problem. This resulted in the identification of a set of core principles, which were refined into a set of building blocks and the interactions between them.

3.3 The building blocks

In our vision problem-solving can be deconstructed into the following elementary building blocks: Read, Analyze, Structure, Select context and formulas, Generate potential solution paths, Solve and Evaluate, and Report final result. Critical Reflection is an overarching block. Our blocks expand upon the four very basic blocks: (1) understand, (2) choose/make a plan, (3) do/carry out the plan, and (4) inspect/look back (Maloney, 2011), (Polya 2004).

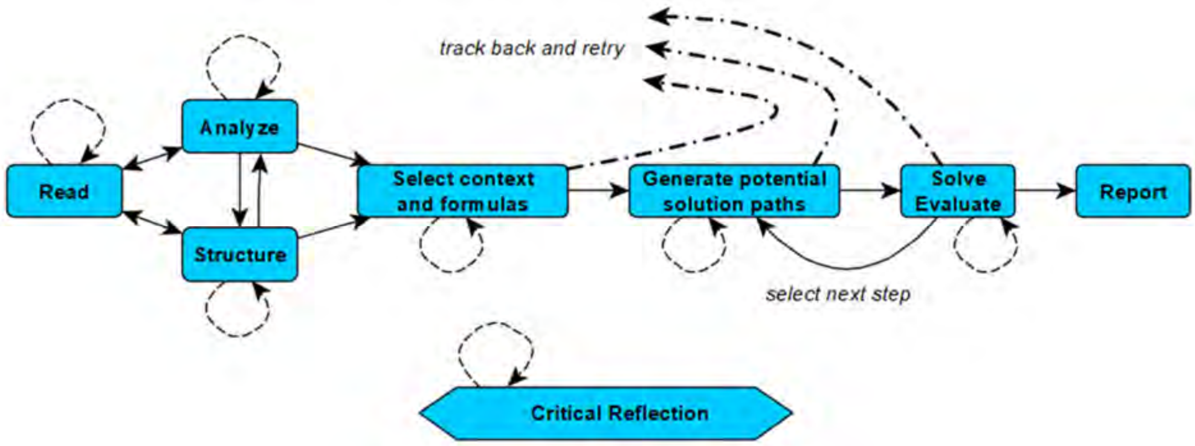

Figure 1: Problem-solving building blocks and their internal control flow.

The central idea is that the blocks do not form a step-by-step plan, but rather a toolbox that can be applied in any suitable order and that can result in a wide tree of approaches to solve the problem at hand. Therefore, the order implied by the solid arrows in Figure 1 is merely a suggestion–unless performing a task. However, when a problem must be solved, there is no direct path from reading the problem description to solving it and reporting the solution. Instead, one needs to figure out possible paths and backtrack when a previous decision turned out to be ineffective. This is denoted by the dash-dot lines.
Equally important are the dashed circles, implying critical reflection and repetition. Critical reflection entails a continuous questioning of the work done: did I read properly, is my sketch complete, is the (partial) solution meaningful, … Also, each building block is probably to be applied several times, e.g. in *Read* one can first scan the assignment to understand the major context and then return to reading when the precise input values are needed; for *Structure* a basis sketch could be made at first, and later on more details can be added. Especially after backtracking, a building block should be reconsidered, e.g. read the assignment again to verify assumptions, select a different context, generate and/or select a different solution path, …
Also notice that after solving a path, the problem solver should evaluate the outcome. When it contains the solution, report it in a proper format. If it is a step in the right direction, select the next step by generating a new path. Otherwise, track back.

3.4 The reported solution does not represent the problem-solving process.

An eye opener to us was the sudden understanding that handing out model solutions for the various exercises did not help students in becoming better problem solvers. The first obvious reason is the absence of different solutions paths, unless many model solutions would be prepared, but more important is the fact that in a model solution the different steps are presented linearly, whereas problem solving is always a back-and-forth process trying out different solutions paths. This simply cannot be made visible in a model solution. We still stress the importance of writing down the final solution in a structured manner, but explicitly position it as a distinct and final phase.

4 APPLYING THE BUILDING BLOCKS IN TEACHING

Although we hinted earlier that uniformly paced on-campus lectures are not perfect, they still are important for introducing the concept and for elucidating it by giving a few examples of different paths that are derived from the same set of building blocks and that lead to the same solution. Next, students solve some problems in class with guidance by the lecturer who always refers to the building blocks as they are applied. We consider the explicit reflection on the concrete stage in the problem-solving process by referring to the building blocks an innovative approach on teaching problem solving skills.

To support the students outside of the classroom, online learning modules were developed for a variety of exercises and contexts. The idea is that students first try to solve the problem without the online module. When the student provides the correct answer, a model solution is presented as an example of how to properly structure a solution. In the case of a wrong answer, feedback is shown and options are given. Just as in the on-campus lectures, we explicitly mention the building block they are currently handling to make the thought process explicit. We thus target a consistent learning experience in respect to the building blocks regardless of the learning lieu (online or on-campus), while at the same time taking care that on-campus and online complement each other. As the covid-era learnt that online teaching simply cannot serve as a full substitute for the social experience of co-learning with fellow students, with our approach we combine the social benefits of on-campus teaching with the benefits of independence and self-pacedness of online learning.

Figure 2 shows a simplified example of a solution tree with different paths. After selecting a path, the learning module continues with options only related to the chosen branch, even if the branch finally would not lead to a final solution, e.g. because of missing data. At the end of the (partial) solution path, the students must evaluate their solution by entering it into the online module. The process of confirming and continuing versus refining or backtracking continues until the student finds a correct solution. Regardless of their position in the module, students can always enter a new attempt for the final solution, to prevent them from having to wade through the rest of the module as soon as they experience the “aha”-moment.

We consider our concept a fine example of intra-exercise adaptivity as depending on the answers and progress of the student, other solution paths are presented that might explore completely different parts of the solution space or that progress at a smaller or faster pace through a similar part with the solution tree.

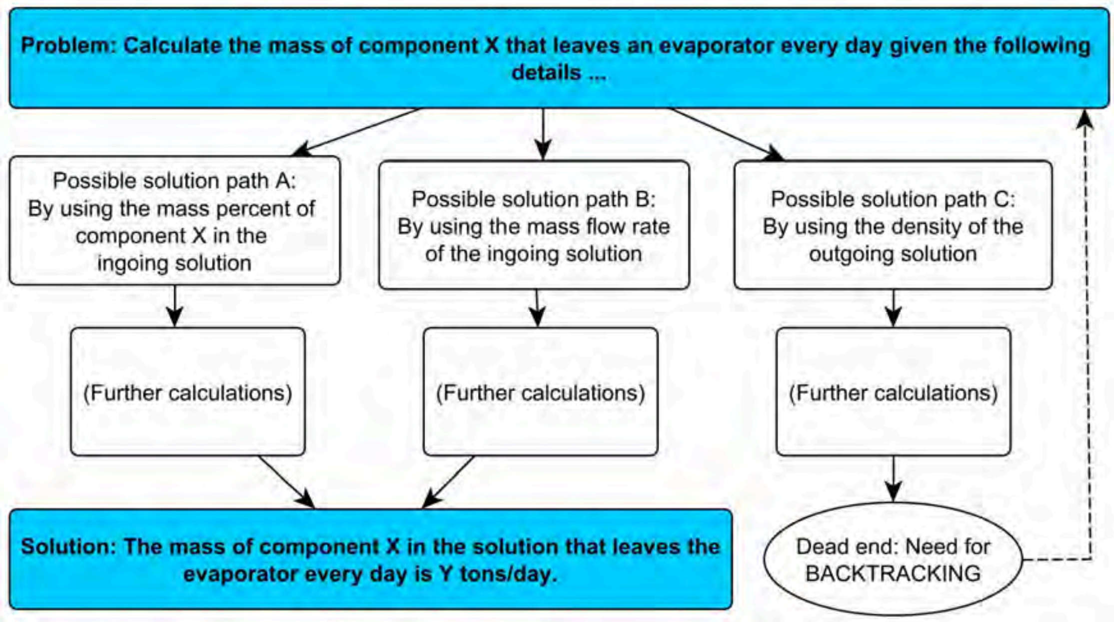

Figure 2: Simplified example of an adaptive solution tree

5 REPORTED EFFECTS

To determine the effectiveness of the online learning modules, we asked all students of the first bachelor year (n = 194) to voluntarily fill in a questionnaire. Most questions used a likert scale, four questions were multiple-choice and two open-ended. Because usage of the modules was also voluntary, some questions were different depending on the number of modules used. 101 students responded, resulting in an overall error margin of 8,90% with a confidence level of 99%. We categorized three groups: no modules used (*zeroMod* group, 41 respondents), one module used (*oneMod* group, 13 students) and two or more modules (*moreMod* group, 47 students). Because the oneMod group consisted of only 13 students, we decided not to withhold this group. In a lot of the domains the students in *zeroMod* and *moreMod* answered similarly, except for the questions in Figure 3. The chances of failing the exam, and being dissatisfied with the results are almost double In the *zeroMod* group compared to the *moreMod* group. This can probably not be solely attributed to using the online modules as students in *zeroMod* probably also practice less when off-line. However two facts at least give an indication of the perceived value of the modules: 1) that 17% of the *zeroMod* group regrets not having used more learning modules and 2) that 34% of the *moreMod* group is convinced that they got a better grade thanks to the modules.

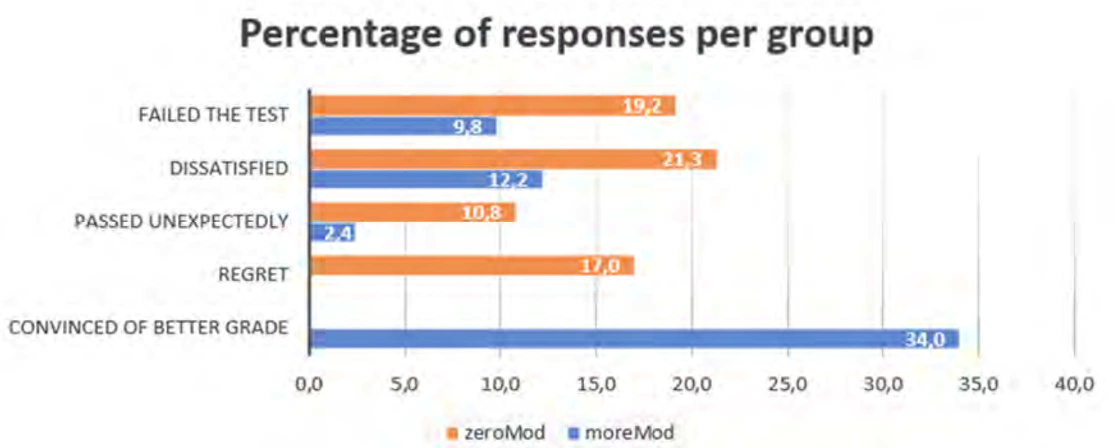

Figure 3: Different answers between zeroMod and moreMod group

We also asked questions similar to Göller et al. (Göller et al. 2017), where 80% of their users found the tool with multiple solution paths helpful in understanding the mathematical concepts, and 40% stated that without the tool they would not have passed the exam. Table 1 shows distinctly lower figures for *moreMod*: 46,3% resp. 4,8%. Looking at the students who barely passed the test and thus need to learn more, this rises to 60% resp. 20%.

	moreMod	*moreMod* barely passing	Göller et al.
Found the tool helpful	46%	60%	80%
Not passing test without tool	5%	20%	40%

Table 1: Reported effect on learning

Further qualitative support could be found in the open-ended questions. The students praised the format in comments as '*Step-by-step guidance'* and '*You can get help and informative feedback when stuck*'. One student put it this way:

> *"I find the online modules very useful because I can clearly see the steps here and I also learn a lot from them."*

The immediate feedback and the proposed proactive approach with hints ensure a good pace in practicing and solves challenges commonly associated with remote learning, where students might drop out of frustration when struggling and void of help or feedback.

Regarding the concept they wrote: '*You are encouraged to search for solutions yourselves'* and '*It encourages logical thinking'.* This fits well in a blended context where you can subsequently challenge the students in-class. The free flow is also appreciated: '*You can skip the feedback steps and just enter the final solution*'. Despite our observation earlier that *only* handing out model solutions does not help students in becoming better problem solvers, students still value them: '*The structured example reports at the end.'*

6 THREATS TO VALIDITY AND FUTURE WORK

A first threat is the socially desired behavior with students unconsciously giving the answers that please their tutors. More important is that we asked about their opinion without really measuring the effect, e.g. whether they think their problem-solving skills improved. To tackle this we will look at the rubrics presented by Docktor et al. (Docktor et al. 2016) and the quantitative measurement of Voskoglou and Perdikaris (Voskoglou and Perdikaris 1993). Another threat is that we tried to let all students participate whereas the central idea of the modules and adaptivity in general, is that only the students who really need it, would use the modules. It is however more likely that the results will only improve when only the correct target groups use the modules. Complaints such as "*It takes too long", "I don't need the modules"* would then disappear.

We also plan further improvements, notably adding more intra-exercise paths, particularly in applying backward thinking, i.e. recoiling from the desired end point to the start; in tracking progress throughout the solution tree and in giving timed hints. The idea is to make estimations of the time needed to progress to a certain state, and to pop up a hint box (with spoiler alert) "*Do you want a hint on topic X".* This somehow resembles the approach by Harskamp and Suhre where students can ask for hints (Harskamp and Suhre 2007), but our approach is proactive instead of waiting on the initiative of the student.

7 CONCLUSION

This paper presented a deconstruction of problem-solving into a non-linear schema consisting of a toolbox of eight building blocks that expands upon previous work with typically four of five basic blocks. The scheme was introduced in a complementary approach for on-campus exercise classes and online learning modules with a focus on consistent reflection on the usage of the building blocks and targeted at blended learning. The intra-exercise adaptivity and multi-path solution trees support divergent thinking and provide the right level of feedback to ensure that students are able to reach a solution.

A survey with 101 respondents out of 194 invites shows that the chances of failing for the tests decreased strongly for students who used at least two modules compared to students who didn't use any modules. The open questions gave further qualitative evidence on the effectiveness of the approach, supporting the claims of the authors to expand the approach. Follow-up research focuses on optimizing the existing modules, developing more developing more modules. Assessing more formally the long-term effects, i.e. the actual increase in problem-solving skills, is also still needed.

8 ACKNOWLEDGEMENTS

Thanks to the students, the team of BES, and the support of KU Leuven Learning Lab, for granting and financially supporting the ZIP-MIPSi-project under the call *Innovatief Digitaal Leren 2021*.

ABSTRACT

This paper reports the authors' experiences integrating sustainability, creativity, and entrepreneurship in engineering education at Aalto University under the project called the Aalto Co-Educator team. The Aalto Co-Educator team was formed to support the university strategy application into education through three main actions: course development, curriculum development and competence development. The goal of this paper is to share engineering educators' experiences in providing sustainability, creativity and entrepreneurship education to engineering students in a rapidly changing nature of work.

Introduction

Competence requirements for engineering graduates are in transition due to a rapidly changing world and global challenges (e.g. Fomuyam, 2019; Hadgraft, Kolmos, 2020; World Economic Forum, 2020). Aalto University has adopted a strategy that addresses these challenges and aims to shape a sustainable future[2].

[2] For more information about Aalto University strategy, check www.aalto.fi/en/strategy

The strategy defines three cross-cutting themes: *Solutions for sustainability*, *Radical Creativity* and *Entrepreneurial mindset*, with the goal of impacting all university activities, including research, education and operations. This paper discusses the experiences in integrating these themes into education through a project called the Aalto Co-Educator team[3]. The study sheds light on activities at all levels in the university organization from university top management to schools, programmes, and courses.

University level – Appointing and resourcing a task force

Strategy implementation in an autonomous and self-steering university organisation is not possible using a top-down approach alone. Instead, strategy implementation activities are needed at all levels of the organization. To address the strategy implementation challenges related to education, Aalto University set up the Aalto Co-Educator team project in August 2021. The project team members comprised of teaching development experts with foci in sustainability, entrepreneurship, creativity, collaborative teaching in courses, and experts in programme development. Aalto University works on 2-year study periods. The next period will cover 2024 (autumn) to 2026 (spring). The program-level planning for the 2024-26 study period ends during the 2023 fall term while the detailed course planning continues in 2024. The project is working towards integrating the three cross-cutting themes into the 2024-26 study plan with pilots and development work ongoing in 2021-22.

Aalto University consists of six schools: (1) Arts, Design and Architecture, (2) Business, (3) Chemical Engineering, (4) Electrical Engineering, (5) Engineering, (6) Science. In these schools, education happens in several independent bachelor, master and doctoral programmes. While programmes and courses have significant autonomy and can independently define their intended learning outcomes, the Aalto Co-Educator team's goal is to ensure that the integration of the cross-cutting themes happens in practice and that students receive sufficient education in sustainability, creativity and entrepreneurship.

Aalto Co-Educator team activities

Once established, the team needed to elaborate on the meanings of the three cross-cutting themes in education. The need for translating the strategy language into teaching terms became evident during the piloting stage when the team was working with teachers on courses and with programme directors on programmes. The team

[3] For more information about the Aalto Co-Educator team, check www.aalto.fi/en/co-educators

needed to develop answers to questions such as: What is radical creativity? What do we mean by sustainability? How are these themes relevant to teaching?

Formulating responses to these questions was an iterative process between the team and the teaching faculty. The first iterations of this process analysed the competencies associated with the three themes. This phase was based on literature (e.g. Wiek, Withycombe, Redman, 2011) and practical experiences of the team members in integrating the themes in education.

One intermediate stage of the evolution is visualized in Figure 1 below. This version presented one Intended Learning Outcome (ILO) for each of the cross-cutting themes (violet circles): Understanding and addressing sustainability-related challenges, driving viable solutions to open-ended challenges (entrepreneurial mindset), and being able for creative teamwork (radical creativity). These high-level themes have then been broken down further into more detailed topics - e.g., systems thinking, futures thinking (Wiek, Withycombe, Redman, 2011), experimenting and decision making. The interesting observation here was that the breakdown of each of the 3 top-level themes resulted in the same or very similar topic breakdown, supporting the notion that the three cross-cutting themes can and should be managed together for inclusion in education.

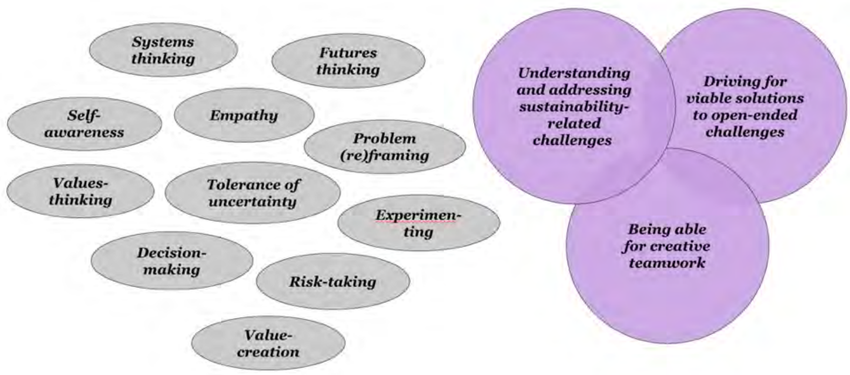

Figure 1. Competencies under the cross-cutting themes

After understanding the main topics derived from the cross-cutting themes, the goal of the Aalto Co-Educator team was to establish intended learning outcomes (ILOs) for programmes and then for courses. In this process, the team noticed how these three topics presented clear overlaps in terms of learning goals and how counterproductive it would be to consider them separately. For example, ‘ability to identify challenges, ideate, experiment, and implement feasible, user-centric interventions’ resonate both with the entrepreneurial mindset and radical creativity. By building broader ILOs that encompass the three cross-cutting themes, the team managed to develop a “language” that facilitated the process of applying and integrating these topics into programmes and courses. This result is shown in Table 1 (next page).

Understanding and addressing sustainability-related challenges	**Driving for viable solutions to complex challenges**	**Nurturing creativity in teams and individually**
Knowledge of sustainability-related challenges and their systemic nature. Ability to contribute with one’s field-specific expertise to shaping a sustainable future.	Ability to identify challenges, ideate, experiment and implement feasible, user-centric interventions. Capability, courage and perseverance for acting in an environment of risks and uncertainty.	Ability to provide alternative framings and seek novel perspectives. Ability to participate in and facilitate creative processes and to collaborate across disciplines.

Table 1: Cross-cutting themes integrated into three ILOs.

Parallel with establishing how the cross-cutting themes are translated into ILOs, the Aalto Co-Educator team started to build connections with different levels in such a complex and distributed organization. Table 2 lists the types of activities that the project team engages in at different levels of the university.

<table>
<tr><th>University level</th><th colspan="2">Activity</th></tr>

</table>

Table 2: Aalto Co-Educator team activities in the university.

Figure 2 below represents how the Aalto Co-Educator team conceptualises its work: teachers develop their skills in competence development, which are transmitted to students in programmes and courses. The implementation of the strategy into education aims at better preparing students for shaping a sustainable future. In practice, integrating sustainability, creativity and entrepreneurship in education, and therefore promoting student learning in these topics, is the focus of the Aalto Co-Educator team in three different types of actions. (1) Programme Development, where the team collaborates with programme directors to define the program ILOs and curriculum (2) Course Development, where the Aalto Co-Educator team works closely with teachers to ensure that the programme-level ILOs are implemented in the planned courses and (3) Competence Development, where we support pedagogical training experts and develop one course for the formal pedagogical training track for university teachers. We will describe each of these three types of activities over the next paragraphs while also pointing out examples.

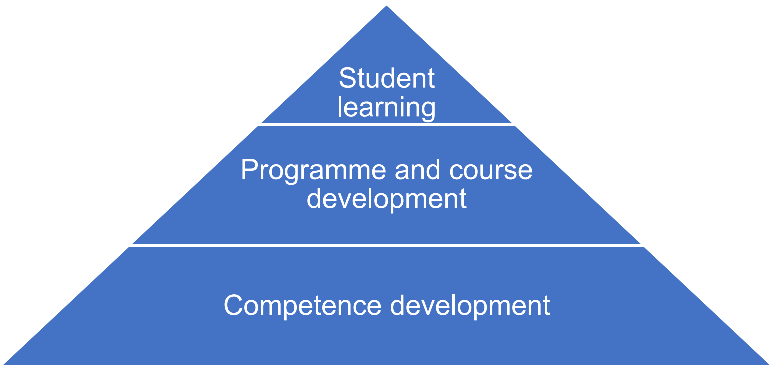

Figure 2: Aalto Co-Educator team works towards student learning

Programme development

At the programme level, one commonly applied solution for introducing a new topic is to introduce a new course. However, the Aalto Co-Educator team aims to integrate sustainability, creativity and sustainability as meaningful and fitting elements in the curriculum courses. We hypothesise that as a separate course, the themes will remain separate while as part of the core courses, the themes merge into the field-specific expertise.

While in course development, the Aalto Co-Educator team works with individual teachers on their courses. In programme development, the team takes a holistic view of the programme: its objectives, learning goals and courses. Similar to what was described in course development, the goal is to identify meaningful connections between the programme objectives with sustainability, creativity and entrepreneurship.

In practice, the Aalto Co-Educator team engages in discussions with programme managers and the teaching team to collaboratively identify how the connections between sustainability, creativity and entrepreneurship can happen. Examples of tools used by the Aalto Co-Educator team in programme development are, for example, curriculum mapping and workshops with the teaching team. Below is one short example of refining ILOs with the support of the Aalto Co-Educator team.

Case example: Programme dialogues in an engineering school

One of the four engineering schools at Aalto University decided to have dialogues with all the programme directors at the school. To date, the dialogues with the directors have continued as a) a reflection dialogue with a programme director, b) facilitation of a workshop with the directors of the majors in a programme, c) sustainability integration in a central high-reach course.

Course development

The actual implementation of the university strategy, and its three cross-cutting themes, into education happens in courses. The strategy does not mandate that every course implements some or all cross-cutting themes. Instead, program development should identify a (small) set of relevant courses that will be used to deliver the program-level ILOs.

The Aalto Co-Educator team works together with the course teaching team to identify meaningful connections between the course content and practices with sustainability, creativity and entrepreneurship. In practice, this means that the Aalto Co-Educator team meets with the teacher(s) in charge of a course for a discussion on what the course learning objectives are and how sustainability, creativity and entrepreneurship can be integrated. An important note is that the teacher(s) in charge have a key role in establishing the connections, while the Aalto Co-Educator team takes the role of facilitating the discussion.

After the discussion with the teaching team, the activities for integrating sustainability, creativity and entrepreneurship in the course are planned. One option is that one of the members of the Aalto Co-Educator team member teaches one (or more) sessions in the course (co-teaching). Another option is that the Aalto Co-Educator Team identifies an expert in the university (or outside) to teach the course. A third option is that the Aalto Co-Educator team only joins the planning of the activities (co-development), where the teaching team takes responsibility for teaching elements of sustainability, creativity, and entrepreneurship in the course. Below, we briefly present one example of a course supported by the Aalto Co-Educator team.

Case-example: Hands-on project course in electronics.

The *Sähköpaja* (Electrical Workshop in English) course is an innovative project course, which is mandatory for the majority of the students at the School of Electrical Engineering. The student teams ideate, develop and build an electrical device during the course. The topics integrated into the course are a prototyping session, exercise and reflection to support the visualizing and testing of an idea as topics of entrepreneurial mindset and radical creativity themes. Sustainability topics presented were environmental impacts associated with the life cycles of electrical and electronic products and the eco-design tools applicable. The student teams reflected upon the themes in a separate session.

Competence development[4]

Building competencies in sustainability, creativity, and entrepreneurship for the teaching staff at Aalto University is a goal shared by the Aalto Co-Educator team and pedagogical specialists across the university. The Aalto Co-Educator team provides support for teachers on these topics and how they can be integrated into their courses and programmes. In addition to that, the Aalto Co-Educator team collaborates with pedagogical specialists from different schools in co-design and co-execution of school-level teaching development activities.

One example developed by the Aalto Co-Educator team is the development and execution of the course Sustainability in Teaching, as part of the pedagogical training for teaching staff at Aalto University. The 3 ECTS course runs twice a year and offers up to 20 teaching staff members the opportunity to identify and apply different approaches to integrate sustainability into teaching. Some of the topics covered in the course are the relevance of sustainability for participants' specific fields, identifying key areas of sustainability relevance, sustainability in higher education, key competencies of sustainability education and how to cope with student anxiety regarding the sustainability crisis. The course has received positive feedback from teachers over the last few years.

Lessons from integrating sustainability, creativity and entrepreneurship into courses and programmes

Implementing a university strategy in education does not come without challenges. However, the experiences of the Aalto Co-Educator team reported in this article can serve as guidance for other engineering educators who aim to integrate

[4] For more information about competence development in the Aalto Co-Educator team, see Schönach, Jaakkola, Karvinen (2023).

sustainability, creativity and entrepreneurship into their educational programmes. Below, we summarize our key takeaways for fellow educators.

- *The translation from strategy into education is not straightforward*. Collaboration with programme staff and teaching faculty was essential. Together, we translated the strategy terms into the language and terms used in the teaching development in the form of ILOs, content topics and teaching methods.

- *Staff support is an ongoing need.* Even after the Aalto Co-Educator team managed to translate the strategy terms into ILOs, teaching staff could not simply implement them. Instead, it required further resources and capabilities from the Aalto Co-Educator team on how to meaningfully integrate the cross-cutting themes into education.

- *The three levels of support - course, curriculum and competence development - offered by the Aalto Co-Educator team proved to be useful for tailoring the support for different staff needs*. For example, teachers in charge of courses and programme directors have different needs (and reach) in terms of the integration of new topics into their teaching. We discuss these three different levels in the next items.

- *Curriculum development proved to be essential to get the mandate and priorities from the schools' teaching leadership*. The dialogue with the programme directors called for thorough background work on the programme goals and courses. Having an overall picture of the programme content and the strategy terms in the form of ILOs facilitated the discovery of meaningful connections between the themes and programmes.

- *Course development is the place where the integration of sustainability, creativity and entrepreneurship happens in practice*. In other words, students meet these topics in practice within the actual coursework. Thus, course integration needs to be directed at the courses with a high reach of students and/or mandatory courses, due to being a resource-intensive activity.

- *Competence development, in the form of a pedagogical course, has proven to function as a platform for competence development*. More specifically, it strengthens the teachers' confidence in teaching sustainability topics and builds connections within the teacher community.

In conclusion, as the Aalto Co-Educator team activities will end at the end of 2024, we acknowledge that the journey of educating engineers on sustainability, creativity, and entrepreneurship cannot be restricted to a single project. It requires continuous support from universities and should be viewed as an ongoing, iterative process. Therefore, we encourage academic institutions to consider the long-term horizon of their support systems, beyond the conclusion of specific projects or teams.

CONTINUOUS ASSESSMENT IN ELECTRICAL POWER ENGINEERING FOR MARINE ENGINEERS

J. Ehnberg[1], S. Lundberg
Department of Electrical Engineering
Chalmers University of Technology
Göteborg

Conference Key Areas: *Curriculum development, Innovative teaching and learning*
Keywords: *Electric power circuits, Electric power systems, Learning outcome*

ABSTRACT

To tackle the climate challenge, all sectors need to contribute, including electrified shipping. Electrified shipping is not only propulsion but also loading and unloading equipment. This transformation requires increased skills and understanding of electric power engineering for the personal onboard, not least for the marine engineers. Therefore, a changed in the curriculum was needed. However, when more theoretical course content was added to two consecutive courses, the student view and passing rate dropped. Although the student view improved quickly, the passing rate recovered slower. To address this issue, continuous assessment was introduced to counteract the drops. The aim of this study was to evaluate the theoretical parts and determine if continuous assessment could contribute to improve student learning and increase passing rate. The students expressed satisfaction with the changes, and the passing rate has increased. Most students also claimed that they learned more compared to standard assessment methods.

1 INTRODUCTION

The trend of electrification of propulsion (Kersey, Popovich, and Phadke 2022) has also come to the shipping industry even though it is delayed compared to many others part of the society. This is mainly due to technical challenges like size, weight and cost of batteries (Kersey, Popovich, and Phadke 2022), but now the development goes fast and the number of fully electrified ships worldwide is increasing rapidly, especially in the Nordics countries (Tarkowski 2021). But it is not only the propulsion that has become electrified (Wärtsilä 2022), also the loading and unloading of equipment is electrified.

The disruptive electrification transition in the shipping industry put new requirements on the needed skills for all that work in the shipping business, like Marine engineers. A curriculum development project was done in the academic year 2017/2018, in two consecutive 7,5 credit courses in the Marine engineer education at Chalmers University of Technology (Chalmers), based on the Standards of Training, Certification and Watchkeeping (STCW) A-III/1, A-III/2, A-III/6 and A-III/7 (International Maritime Organization 2019). The purpose was to meet the new requirements that the electrification demands while still fulfilling the STCW requirements. In the first course the focus was more on general knowledge on how to handle basic models of electric components, like resistances, inductances, and capacitances, and how to solve more extensive problems. This was done to prepare the students for the more complex systems that are expected on electrified ships, and which will be harder to grasp intuitively. The second course emphasises on models of actual electric components, like electric machines, cables, and power electronics converters, but also include systems aspects on components interaction as well as high voltage. A stronger component influence on system behaviour is expected to be needed to handle the rapid development in the areas of electrification. High voltage was also included as more land connections as well as systems on board are above 1 kV.

The marine engineer students are unique as a student group since they often have more applied view on knowledge and therefore often has low interest and experience of theoretical studies as they are focusing on professional degree (Hindhede and Højbjerg 2022). Therefore, they often do not have a developed and/or an individually adapted study technique which is challenging for the academic teachers (Hindhede and Højbjerg 2022). During the last decade the interest of potential students to the marine engineering program has decreased and since the academic year 2015/2016 all eligible students has been accepted. This has led to a large spread in pre-knowledge and in study techniques, despite no change in admission requirement. The number of students in the course has varied over the studied period between 7 and 53 with a mean number of 31 and 38 for respective courses.

The passing rate of the two courses dropped at the same time as the curriculum development was done, which initiated a development of the assessment process. The desired outcome of the development was to:

- Get the students to work continuously throughout the course.
- Increase the passing rate during the first year of the course.
- Assess knowledge rather than skills.
- Increase the interest in getting feedback, they do not learn from their mistakes.

In addition, there is an extra requirement to show that all learning outcomes was assessed due to the certification according to the SCTW requirement.

A system of continuous assessment was introduced in an attempt to meet the above mentioned goals. Continuous assessment is an ongoing process of monitoring, evaluating, and providing feedback on the progress of student learning over time. It is known to improve student learning by providing ongoing feedback to students and helping them to identify their strengths and weaknesses, so they can make adjustments to their learning strategies (Hattie 2012). It can also encouraging students to stay engaged and focused throughout the course (Rosadoa et al. 2022). Moreover, it can also help the students in breaking down the learning into, for them, more manageable parts and to take ownership of their learning by enable them to set goals and monitor their progress over time. The outcome of continuous assessment has shown to lead to better grades, a higher passing grade and improved engagement in course activities (Korhonen et al. 2022). However, there are drawbacks (Hattie 2012), like time-consuming for both students and teachers, puts higher constant pressures on the students and it might limit the learning with a too narrow focus on the assessment in the learning situation.
The main outcome of this paper is to find out to what extent continuous assessment can support marine engineering students to meet the new requirements that the electrification demands through more advanced studies in electric power engineering.

2 METHODOLOGY FOR REVISION AND EVALUATION OF THE ASSESSMENT

The first course, basic electric power circuits course (BEPC), is given in the second half of the first semester during the first year. The second course, Electric Power System and Component course (EPSC) is given in the first half of the first semester in the second year. The implementation was done step-wise, first in the BEPC due to a more pressing situation and then in the EPSC.

2.1 Basic Electric Power Circuits

Previously the assessment was three laboratory work and a written final exam. During an intermediate period of two years, three small exams were provided during the course, giving bonus points to the written final exam. Since 2020/2021 the written exam is divided in three parts, A) on DC circuits, batteries and cables, B) on AC circuits and C) on three phase system, the DC machine, and transformers. Each part counts for two credits each. The three laboratory work are kept as before and gives 1,5 credits. Students that have passed one part, does not have to remake that part. The final grade is determined by the total points of the three parts, but at least 50 % is required on each part. The three laboratory work are all 4 hours long and has been the same since 2017/2018, first part is on DC, the second is on AC and the DC-machine and the third is on the three phase system and the transformer.

2.2 Electric Power System and Components

Previously, the assessment was divided into three parts, five occasions with laboratory work, three short hands-in related to regulations at sea and a final written exam. Since 2022 the written exam is replaced by three hand-ins. To verify that the students have answered the hand-ins themselves there is an oral follow-up. If the students pass the follow-up, they get grade 3 on that hand-in, which is the lowest grade for pass. For higher grade, a more traditional oral assessment is done. The five laboratory works are the same since 2017/2018: the first is on the synchronous generator and generator operation in a small power system, the second is on the asynchronous motor including starting methods, the third is on power electronics and converters, the fourth is on high voltage phenomena and the final is on cable sizing and protection settings.

2.3 Evaluation

For the entire studied period 2013/2014 to 2022/2023 the answers on the anonymous written standard evaluation form of the university are used. The data from these forms are used for the long term and trend studies. As completement an extra anonymous written evaluation was done during 2022/2023 just before and after the EPSC. Data regarding grades and passing rate were retrieved from the national student administration system, available via the public principle.

3 RESULTS

In the written standard evaluation form, there is one question where the students are asked to rate the overall impression of the course, from grade 1 very poor to grade 5 excellent. In Figure 1 the average overall impression of the BEPC and EPSC together with the average of the yearly overall impression of all courses in the program are shown.

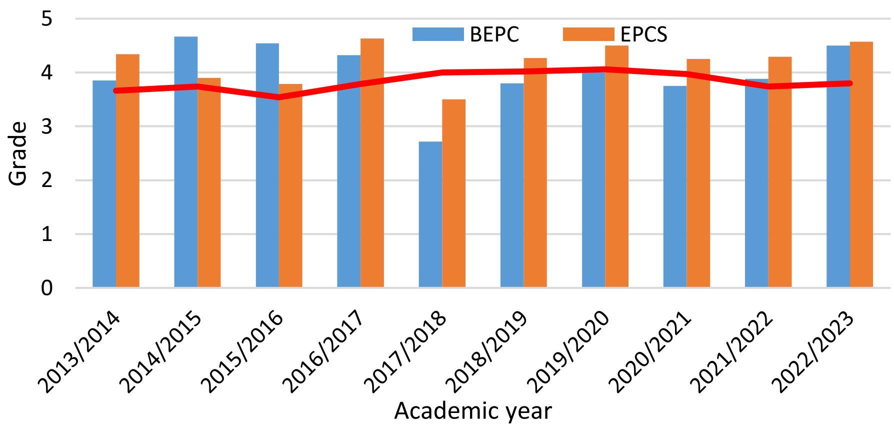

Figure 1. Average overall impression of the BEPC and EPSC and the yearly average for the marine engineering program at Chalmers. The scale is from grade 1 very poor to grade 5 excellent.

As can be noticed in the figure there is a significant drop in the overall impression for year 2017/2018. That year the teaching staff and the examiners of both courses were replace together with that the curriculum was developed. The large drop was restored the year after and the courses has returned to be better than the program average, though it took longer time for BEPC to recover.

In Figure 2 the grade distribution for the BEPC is shown. The result is the total after the three possible attempts to pass the exam(s) of the year they registered for the course. The results are the combined distribution of all the three possible exam occasions during each year. The grading scale is that grade 5 is for between 100 % and 83 % of the total number of points, grade 4 is for between 83 % to 67 %, grade 3 for 67 % to 50 % and the student fail, grade F, if the summation of the points scored on the tasks are below 50 % or not all parts has at least 50 %. As can be seen in the figure the failure rate has increased from 2016/2017 and the distribution of students with the highest grade has also decreased compared with the earlier years. As mentioned before, in 2020/2021 the final exam was divided into three smaller exams and from Figure 2b) it can be noticed that the failure rate has decreased from 2020/2021 and the number of students that got the highest grade have increased, at least in study year 2020/2021. As can also be noticed in the figure there are some students that have passed two and one of the three exams. This means that these students can focus on the remaining exam or exams and do not need to study for the part/parts they have already passed. It should be highlighted that the number of students in the course in study year 2018/2919 was much lower compared to the other years.

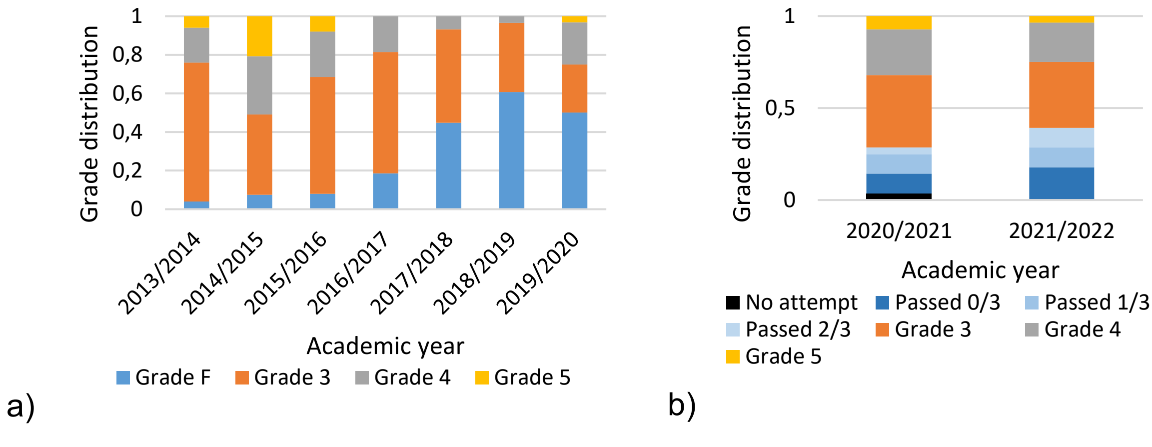

Figure 2. Grade distribution for the BEPC, where a) is for 2013/2014 to2019/2020 and b) is for 2020/2021 and 2021/2022 where continuous assessment was applied.

In the second course, EPSC, the assessment did not change until 2022/2023. In Figure 3 the grade distribution can be seen. The result is the total after the three possible attempts to pass the exam(s) of the year they registered for the course. However, not all students utilize that possibility. Students that pass the course after the first year after registration are not included in the statistics. It can clearly be seen that the passing rate decreased 2017/2018 due to the content change in the course. In 2022/2023 there was a significant raise in the passing rate and the students that failed did not even tried to solve any of the hand in assignments. The outcome of the new assessment has meant fewer fails and more students with grade 3, but not more students with grade 4 and 5. This probably means that the system does not contribute to grade inflations. Around 80 % of the students stated that they got the grade they aimed for.

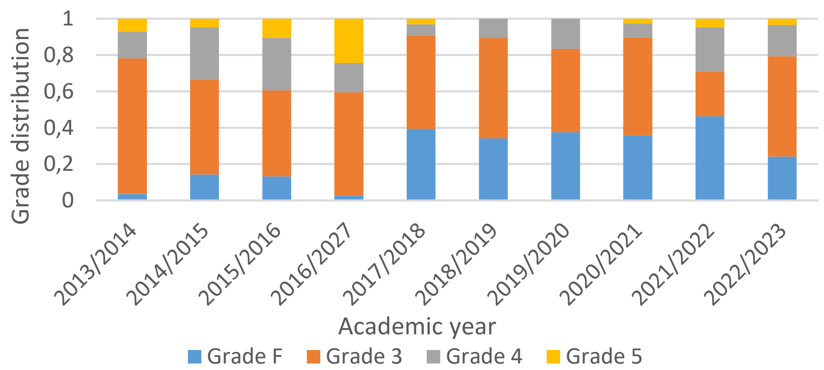

Figure 3. Grade distribution and failing rate for the EPSC

There are two other factors that could contribute to the increased failing rates from 2017/2018 in the two courses. One is that from this year all eligible students were admitted to the program, which means that some students were admitted with low merits. The other factor is that the number of students that has been admitted to the program has been dropping between the years 2014/2015 to 2018/2019 and then the number of students has slowly increased, but only to approximately half of the number of students that was admitted in 2014/2015. This means that the number of students in the courses are low and some of these students have low merits. This could contribute to a decreased passing rate and lower grades of the students. Unfortunately, it is not possible to differentiate these effects form the effect of a new course setting and teachers.

In Figure 4 the student view on the relation between the assessment and the learning outcomes are shown. The question deals also with the expectations of the assessment as it has a high correlation with the result of the assessment.

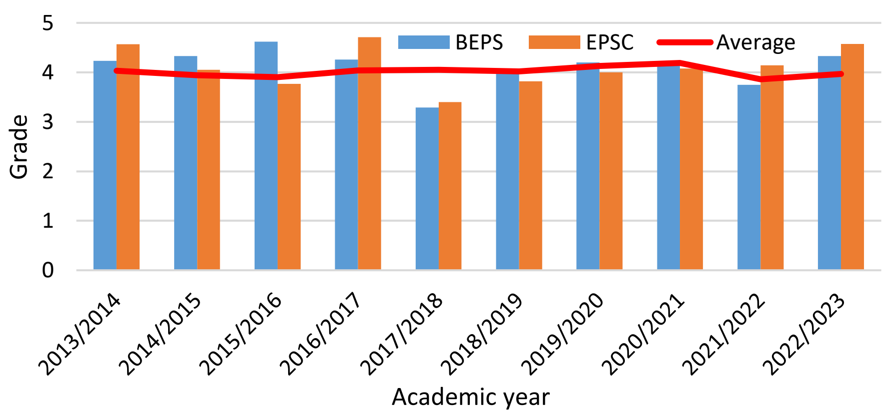

Figure 4. Students grade (1-5, where 5 is the highest) on however the assessment of the course is related the learning outcome of the course.

Overall, the student thinks the assessment is suitable for both the courses. There is also here a drop in 2017/2018 followed by a recovery that levels out, but for the last year there is another step in the right direction.

It can be seen that students prefer the continuous assessment, but the different set-ups fit different students. As was expressed by a student:

> *"Good new take on the exam, it promotes learning!"*
>
> Anonymous student taking EPSC in 2022/2023, translated from Swedish by the authors.

On a direct question if the student learned less, the same or more due to the new set-up in the EPSC, 95 % stated that they learned more and the last 5 % stated that he/her learned less. The claimed higher degree on learning and also higher passing rate, see Figure 3, can be explained by the reoccurrence of learning opportunities, during the teaching, at the hand-ins and then as preparation of the oral follow up. Another explanation is that the students were stressed for the oral follow-up, so they did not dare to show up unprepared. Almost half of the students claimed that the oral follow-up was stressful, but some also claimed that written exams can be stressful.

4 DISCUSSION

When introducing continuous assessment in the two courses also the structure of the courses was adapted for this. The courses were divided into smaller parts and all teaching elements that supported the students learning of one part was given before the next part was started. The assessment of the part was done approximately a week after all teaching of the part ended. It was done in this way because the later parts build on the previous parts in the course. Since the assessment is close to the end of the previous part the students should have a good understanding of it so they can use it as the base of the following part. In this way the course structure helps the students with a preferred order of learning. The division into smaller parts also means that the amount of material that needs to be studied for each assessment is smaller and this can make it easier for the students since they have a limited part of the course material to study for each assessment. For the BEPC, from 2020/2021, the students also get each part reported individually and after completing all the parts they get a final grade on the course. This means that if a student fail on one part, the student only needs to study that part again and take the reexam for that part of the course. This helps the students to know which part and which material to focus on. From Figure 2 and Figure 3 it can be seen that the failing rate increased when the curriculum was developed, but it has decreased since. From Figure 4 it can be seen that the students thinks that the assessments tests that they reach the intended learning outcomes of the course and if the students mark this question with this high numbers, it usually means that they also think that the assessment is fair. From Figure 1 it can also be noticed that the overall impression of the courses is good and if the grading of the course is this high it usually means that the students like the course. It is good courses with fair assessments, but difficult.

The continuous assessment provides continuous feedback on the progress of the student, especially related to the passed parts. However, for the not passed parts it is more problematic, apart from the actual result, especially for the BEPC. In the course the students get an example of a solution for the exams and are invited to discuss their solution with a teacher, but no one has ever done that. In the EPSC the students need to, and do, address the not passed part to not fall behind in the assessment process.

Moreover, using different assessment methods can provide a more comprehensive and accurate picture of an individual's abilities and strengths (Suskie 2018). Therefore, it's important to choose an appropriate range of assessment methods for everyone, to help them maximize their learning and achieve their potential.

Oral communication, trained in the oral follow-up, is essential for marine engineers, particularly in situations where safety and efficiency are paramount. By prioritizing effective oral communication, marine engineers can perform their duties more effectively and minimize the risk of accidents and other safety incidents (Ahmmed 2018; Øvergård et al. 2015). But training in verbal communication is also important for the sometimes stressed psycho-social environment onboard, which may occur due to fact they work close together for longer periods of time (Thorvaldsen and Sønvisen 2014).

5 CONCLUSIONS

The developed assessment methods make/forces the students to work continuously throughout the courses and might have contributed to the increased passing rate. The oral follow-up focuses more on knowledge then the skills and practice technical oral communication but is quite stressful. It also gives an opportunity to give direct feedback on any misunderstandings in a way that is hard to do in writing. At least in the EPSC the students really read and sometimes even discuss the short comings in their work.

ACKNOWLEDGMENTS

The authors would like to acknowledge all the students that has taken the courses throughout the years.

ABSTRACT

Sustainable development and the UN's Sustainable Development Goals have been pointed out as crucial for our common future, addressing several aspects of a world to be considered as sustainable. From a university perspective it is certainly interesting, and important, to see how research and education contribute to that context, which may be seen from both disciplinary, and multi-disciplinary perspectives.

A one-year Master Program in Computer Science for Sustainable Development, at Kristianstad University (HKR), Sweden, has a background in the UN's Agenda 2030, and in statements, claiming that 'at the edge'-techniques, from areas such as Artificial Intelligence, and Datamining are crucial to approach each and one of Agenda 2030's 17 Sustainable Development Goals. With this background, that Master program, was initiated to provide, for students at a master level, challenging disciplinary subjects, as well as an interesting and valuable context to contribute to, with their technical skills. To furthermore approach the students' maturity in the field, the program is supported by courses regarding, on one hand (1), Sustainable Development, and how Computer Science generally may contribute, and on the other hand (2), advanced projects where concepts and techniques shall be practiced within research contexts. It shall also be mentioned that the program is open for students internationally, thus bringing further interesting values through the mutual sharing of experiences from international perspectives. This contribution intends to provide an overview of the program, as well as a more in-depth presentation of the two above-mentioned courses.

1 INTRODUCTION

The United Nation's Agenda 2030 was adopted in September 2015, and explicitly pointed out 17 Sustainable Development Goals (the SDGs) to be achieved in 2030. While those goals ([1]) address several critical areas, such as, *No Poverty*, *Zero Hunger*, and Good Health and Well-Being (SDGs 1, 2, and 3), one goal especially addresses cooperation to accelerate the achievement of the SDGs, that is, goal 17, *Partnerships for the Goals*. Today, there exists a number of national as well as regional Sustainable Development Solutions Networks (SDSN) ([2]), and where especially SDSN NE (NE stands for Northern Europe), organizes the northern nations of Europe, including Denmark, Finland, Norway, and Sweden, for cooperative actions in the context of Agenda 2030.

The launch of SDSN NE took place in Gothenburg, Sweden, in February 2016. HKR (the home university of the author) was represented by the author of this paper (amongst others). At that launch, Swedish business and political leaders were invited to participate, along with engaged academics and representatives of several organizations, such as the UN and the Swedish International Development Cooperation Agency ([3]), showing the high ambitions for the SDSN NE, as well as for the Agenda 2030 at large. At that meeting, furthermore, IT was singled out several times as essential to achieving each of the 17 SDGs. Not only was IT mentioned in general, but cross-cutting techniques such as Big Data, AI, and the Internet of Things (IoT) in particular ([3]). It can be mentioned, IT or Computer Science, does not explicitly correspond to any of the SDGs but is nevertheless considered to be crucial for the fulfilment of each of them ([4]).

Meanwhile, at that point in time, the Dept. of Computer Science at HKR (CS@HKR) was struggling with its previous master program in computer science. That program should have a focus on Embedded Systems but was rather diffuse in nature and difficult to get a comprehensive understanding of. It was therefore perceived as a need to revise the master's program in order to have a clearer and more well-motivated structure. The launch of the SDSN NE could in this context be seen as a source of inspiration to revise that master program in a direction towards how Computer Science (and IT generally) may contribute to Sustainable Development (SD). In such as program, concepts of SD would in that case be emphasized, and interesting and valuable techniques addressed.

1.1 Meeting Legal Demands on Sustainability in Education

Regarding this contribution from another perspective, the Swedish Higher Education Act ([5]) clearly states that SD should be considered at the Swedish universities, and that concepts of SD should be included in the universities' various courses. In 2017, to follow up how well the Swedish universities lived up to those directives, a survey was organized by the Swedish Higher Education Authority ([6]). The result showed a rather depressing result ([7]), only about 25% lived up to the directives, and then about 75% (including HKR) needed to do more or less exhaustive work on course design, as well as on administrative routines to improve their approaches towards SD.

Requirements for sustainable development in the computer science programs were generally difficult to relate to. But with inspiration from the launch of the SDSN NE, it was possible to see that there was in fact a lot that could be approached. Moreover, from the perspective of several technologies, approaching the SDGs could furthermore be seen of interest to students as well as to researchers and teachers.

In the light of the above, in September 2017 it was decided that a revised master's program in computer science should have an overarching focus on SD, encompassing interesting techniques to meet SD, and clearly be related to surrounding societal interests. Like the previous master's program, the revised program should be open internationally, with potentials to contribute to additional values regarding SD. The program is a one-year master's program and was provided for the first time in autumn 2018.

1.2 On Prerequisites for Teaching and Learning on SD

According to [8], Higher Education has a critical role in advancing the agenda of SD, and where educating for SD can be considered a natural way to ensure SD. Already since the Stockholm conference in 1972, the significance of sustainability ([9]), in Higher Education has been recognized for its important role in fostering society towards SD. Still, as pointed out by [3], barriers emerges when higher education institutions do not establish incentive systems that promote changes at the individual level. Lack of time, and administrative support, thus, make it difficult to integrate SD in higher education institutions ([3]). The re-designing of curricula is a relatively easy part, but efforts that imply organizational members to hold shared assumptions about SD and take the lead in society demand something else ([8]).

The demands for improvements on SD at HKR, were primarily approached through an investigation into the circumstances of HKR, and suggestions on how to improve ([8]). In a report resulting from that investigation, a pedagogical course for HKR's educators was proposed ([10]), among other things. That course was launched at 2018, piloted with educators from CS@HKR in 2018. It has then been open for all educators at HKR ([11]), thus contributing to inter-disciplinarity, or cross-faculty approaches towards SD ([12]). The course emphasizes SD generally, experience sharing amongst colleagues, and tasks regarding curricula and course development towards SD, all in all to support the educators with capacities for SD teaching and learning at their respective study programs and courses.

2 METHODOLOGY

The one-year Master Programme *Applied Computer Science for Sustainable Development*[1] has as an overall goal that '*the student, after graduation, should be able to work with and lead the development of complex computer-assisted systems with an independent, critical and interdisciplinary overall view, in order to meet the multidisciplinary needs, found in different contexts related to sustainable development*'. To support for this, a structure of the study program must concern aspects on SD, as well as skills in advanced techniques of computer science. Furthermore, to be able to act effectively in contexts of multi-disciplinary challenges, project courses should bind together technical skills and apply those in contexts outside computer science, and with contributions to SD. Furthermore, demands are especially put on master programmes in being research oriented. That is, technique-oriented courses as well as SD-concept-oriented and project-oriented courses must reflect on research themes. An overall structure of the program is illustrated by Fig. 1, and where the timeline of the program follows the numberings of the blocks, and where 'CS methods 4 SD' runs over the whole first autumn semester.

[1] Applied Computer Science for Sustainable Development: One-Year Master Programme - 60 credits, https://www.hkr.se/en/program/computerscience-master

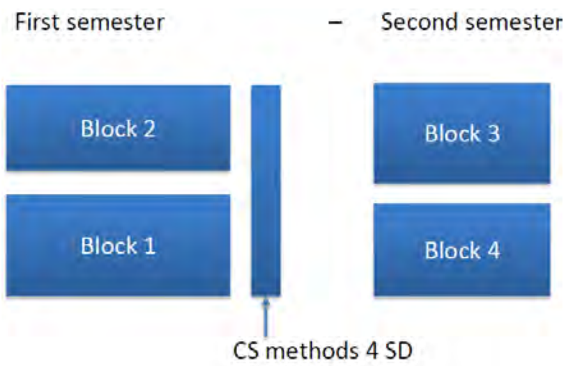

Fig. 1. Outline of a one-year program

Moreover, students should be able to meet challenges where sensor-data in Internet of Things-based systems may reveal, for instance, air quality, or states in agriculture. Data should be collected and withdrawn through methods of datamining and interpreted through AI or Machine Learning. Furthermore, results should be monitored, preferably at handheld devices independent on underlying technology. Also, the communicating data and results should be made secure. Thus, the blocks are furthermore outlined as follows:

- **Block 1**
  - Mobile platform development
  - Wireless communication and security
- **Block 2**
  - Internet of Things
  - Machine Learning
- **Block 3**
  - Project, multi-disciplinary
  - Data Mining
- **Block 4**
  - Thesis Project
- **and also, CS Methods for SD**
  - Generic skills, Science and methodology
  - Self-reflection and self-awareness
  - The context of the Agenda 2030, and Computer Science for SD

This contribution will especially focus on two of the courses that have been given by the author of this paper, that is, *Computer Science Methods and Sustainable Development*, and *Project in Multidisciplinary Contexts*. The structures and main contents are outlined in the sequel.

2.1 Computer Science Methods and Sustainable Development

First, the syllabus of the course[2] clearly addresses the context of SD to the course, and furthermore points out ethical aspects as significant. Second, the course aims to

---

[2] Computer Science Methods and Sustainable Development - 6 credits, https://www.hkr.se/en/course/DT580C/course-syllabus

practice generic skills, such as searching and reading scientific material, and make oral and written presentations. The main components of the course are *Lectures*, *Exercises,* and a *Design Project*.

The lectures are supported by literature with focus on general perspectives on SD[3], Computational Sustainability[4], Research Methodology[5], and several scientific articles, and internet-based material. Assignments of the exercises follow the lectures and shall provide a basis for further understanding. Moreover, the exercises contain elements of self-reflective training, with the intent to support for approaching mature views on SD, and especially on IT for SD. All is presented in the class and discussed amongst the students and the teacher, which should bring even further values to the matters discussed.

Themes of assignments include:

- Design a digital user interface that should be used to inform the common public about SD.
- Study one of the ICT contributions to the 17 SDGs, from *'Fast-forward_progress_report_414709 FINAL.pdf'*, present it to the co-students, and initiate discussions.
- Study articles on ethical aspects, for instance, with respect to the AI revolution coming fast. Present and discuss in class.

Self-reflective training was conducted iteratively during the exercises and were structured around a quite large number of statements, that the students should reflect on individually, and then discuss in class. The individual reflections mostly were summarized in written forms, but also mentimeter-based systems[6] was used. Example of statements follow:

- I think the chosen set of the SDGs is a good representation of how we shall approach sustainable development.
- Computer Science and Software Engineering is absolutely necessary to approach the SDGs.
- The UN is the best-suited organization to be responsible for global issues.
- In my home country, I feel that there is an awareness of the importance of sustainability at large!
- At a personal level, I live a sustainable life.
- Water is clearly the most important sustainability issue.
- IT-based systems could clearly contribute to waste-management, a clean city, and a clean environment.
- All the SDGs are clearly interconnected.

[6] Engage your audience & eliminate awkward silences, https://www.mentimeter.com/

- Self-reflection tests like this clearly contributes to higher levels of maturity when approaching projects with sustainability themes.

It was made clear from the teacher that the students should feel free in their approach to the statements, and not give answers that they think the teacher expected.

Finally, the course focused on a design project, where the main theme for the project was decided upon by the teacher, that is, SDG 11, on *Sustainable Cities*. The choice of that SGD was based upon the inherent complexity of that SDG and that it may be dependent on further SDGs. Still, it was up to the students to take further focus initiatives within the frames of *Sustainable Cities*. A demand was that the students should come up with IT-solutions to an observed problem and design an IT-based architecture that solves the problem. A report shall conclude the project, with a presentation within the class.

2.2 Project in Multidisciplinary Contexts

The course[7] is focused on a main aim of '*design and implementation of projects in multidisciplinary contexts and concepts and techniques for implementing projects in research contexts*.' To meet that aim, student projects have been grounded in applied research projects involving researchers at CS@HKR, where contributions can be seen in contexts of SD. Examples of such research projects include:

1. *Identifying bacteria in drinking water*. The project has involved Microbiology researchers at Lund University[8], as well as representatives of the Ringsjöverket Drinking Water Treatment Plant[9]. The project clearly connects to SDG 6, on *Clean Water*.
2. *Identifying cancer cells in blood samples*. The project was guested by researchers in Bioanalysis at HKR. The project connects to SDG 3, on *Good Health and Well Being*.
3. *Identifying cases of cracks in concrete of bridge fundaments*. The project was connected to Öresundsbrokonsortiet[10], that manages the bridge between Sweden and Denmark, and relates to SDG 11, on *Sustainable Cities* (there is no *Sustainable Regions* amongst the SDGs).
4. *Analyzing movements of mallards in local areas*. The project has been guested by researchers in Environmental Science at HKR, and relates especially to SDG 15, *life on land*.

The projects, that are chosen by the teachers, are conducted through iterative project meetings, where students are guided further through the process of fulfilling their projects. The course ends up with a final presentation by the students, and a final written report. To solve the project problems, the students need to apply techniques

[10] Øresundsbro Konsortiet, https://www.oresundsbron.com/en/about-oresundsbron/about-us/oresundsbro-konsortiet

of courses learnt at the previous semester. Thus, the course lives up to aims for SD, Computer Science research themes, as well as multi-disciplinarity.

3 RESULTS

A program evaluation was conducted by representatives of CS@HKR in 2021, to get an overview insight in students' attitudes towards the program. On a five graded scale, students responded to statements regarding different aspects of the program, where 5 corresponds to the most positive attitude, and 1 to the least. Overall, the students responded very positively, with a mean value over all students and statements of 4.75. A 5 was given to statements, such as, '*The programme syllabus has corresponded well to the actual content of the program'*, '*I have acquired insights about research in many subjects that were covered in the courses'*, and '*Communication with the teachers has worked well in general'*. The lowest value, 4.25 was given to '*I feel that the program content and structure give me good opportunities to get jobs in the IT-sector (programming, consulting, development etc.)'.*

Moreover, all university programs shall be evaluated in regulated ways, including this master program. In 2022 an evaluation of the program was conducted by HKR-internal, as well as external evaluators, from academia and industry. That evaluation concerned both organizational and program-structural aspects and showed a general satisfaction with the program. Criticism and potentials, pointed out though, concerned more industrial contacts with the region's industry, and a strive after a second master year. The most critical point regarded how to attract larger groups of students. The program has suffered from small groups of attending students. Very few of the students at the department's bachelor level show interest in continuing at the master level, the students of the program are mostly attracted internationally.

To meet the criticism regarding contacts with the region's industry, representatives from such contexts will be invited for guest lecturing. It is here considered valuable that such lectures not only present technical aspects of interest, but that those also should have interesting points of connection to the study program with respect to contexts such as SD or the Fourth Industrial Revolution. What was possibly not highlighted during the evaluation was that several of the degree projects were actually done against companies. This also creates opportunities for the students to be employed after graduation, and for the international students to remain in Sweden, which several of them seem to want.

To meet the critical matter of low student enrollment, a more offensive, but still gentle, strategy has been introduced. Applying students have been contacted, and will be contacted continuously, and provided with information regarding the study program, how to live and act in Sweden, and more. The students will be treated as if they already have accepted to take part of the program. Of course, they still have their own free will in their final decisions.

At levels of courses, course evaluations have shown satisfactory results, with the latest mean values provided by students (same scale used as pointed out above), autumn 2022 of 4.4 for the 'methods-course', and spring 2023, of 4.3 for the 'projects-course'. Qualitative judgements include:

- The Methods-course:
    - *I learned a lot from this class. This class allowed me to systematically understand the relationship between sustainable development and computer science, and also exercised my reading and writing skills.*
    - *It is good to know how the computer science is contributing for sustainable goals to make the world a better place to live and the way think to achieve the sustainable goals 2030 is quite motivating and challenging too*.
- The Project-course:
    - *Through this course, I learned how to work in small groups to complete a project. And the projects that this course focuses on are also very interesting. Not only did I learn about technologies such as data processing and machine learning, but also the living habits of some species of ducks, etc., which are very in line with the topic of sustainable development.*
    - *The project meeting we had with guests in middle of the course with guests from environmental department and some faculty from science department it would have been better we have at initial stage*

Getting back to the self-reflecting training of the exercises, as mentioned in previous section, a more comprehensive study on this has previously been made by the author of this contribution and presented at a faculty meeting. It is outside the scope of this paper to dig more in the details, but what is interesting is that students mostly have been positive towards this kind of exercise, which is also shown through positive responses towards the statement '*Self-reflection tests like this clearly contributes to higher levels of maturity when approaching projects with sustainability themes*.'.

An interesting question concerns what happens next with the students. While [8] in first place is addressing how to prepare the university's educators towards effective teaching regarding SD, that report also points out a need for investigating what happens with the students after their education. That is, how do they contribute to future society with respect to SD? Currently it is well known that the students are highly employable, some even continue their careers in academia. Still, the explicit information on the impact by the alumni on SD is rather vague, and as pointed out by [8], clarifying on this is a both interesting and important potential future work.

4 SUMMARY

To sum up: the author of this paper was initially engaged when the SDSN NE was launched and saw an interest in contributions from the field of computer science to approach the SDGs of the UN's Agenda 2030. Furthermore, the author was engaged in investigating proposals on how to meet the criticism towards the home university's lack of ways to manage SD at different levels. One of the proposals addressed a course for educators to guide them in teaching-learning for SD. The involvement in the creation of such a course provided a piece of the puzzle to complete the design and implementation of the revision of a master's program. In that program, computer science students are given the potential to contribute as future agents of positive change.

This paper has reported that the program works well, both at program level and in the courses presented. The students have generally shown interest and satisfaction both in relation to computer science and SD.

In program evaluations, it has been suggested that further work towards industrial contacts is seen as valuable for the program, as well as a striving towards a two-year master programme. A critical problem that the current program has, though, is the low number of attending students, which has caused the program to be questioned and in need of further revisions.

ABSTRACT

The Birmingham Centre for Rail Research and Education (BCRRE) delivers research and education to benefit the international rail industry, including an MSc programme which is designed to equip students with the skills needed to lead multidisciplinary engineering projects. The authors are trying to apply some of the systems thinking taught in the programme to the programme itself. It is established practice to maintain learning outcomes for an educational programme and we do that, but we describe how we are trying to improve the information available to us about what the industry wants and the varying needs of our student population. Our information-gathering processes are not just passive feedback loops but are actively focussed on areas of interest. We are also using the V diagram (a systems engineering concept) as a framework for maintaining line of sight to the full set of

feedback information in order to assemble a richer picture to support more balanced decision-making. We describe how our approach is already producing richer input which we are using to improve our programme and why we are encouraged that our approach can make a positive difference to achieve a better educational experience in engineering disciplines.

1 INTRODUCTION

In this paper we describe our experience of applying some aspects of systems thinking to an MSc programme.

1.1 The Railway Systems Engineering and Integration MSc programme

The Birmingham Centre for Rail Research and Education (BCRRE) delivers education and carries out research that is intended to benefit the rail sector in the UK and worldwide. All three authors work at this institution where we are involved in the delivery of education as well as research into issues related to the delivery of education.

Railways are very interconnected systems. The trains, the track, the signalling, the stations, the timetable and many other things all work tightly together such that changing one part can very easily upset another. The different parts of the railway are looked after by different disciplines. As a consequence, in order to successfully deliver a project that will change the railway, it is necessary to manage the interfaces between the parts of the railway and co-ordinate the disciplines.

In other sectors, such as defence and aerospace, there has been, for more than half a century, a specialist discipline concerned with this management and co-ordination called ‘systems engineering’ (SE). As modern technology drives an increase in complexity and interconnectivity in railways, railways are increasingly coming to realise that they need to adopt the principles of SE in order to avoid expensive mistakes.

BCRRE’s educational offerings include an MSc programme in ‘Railway Systems Engineering and Integration’ (RSEI) on which students obtain a grounding in SE.

1.2 Systems engineering and systems thinking

SE involves obtaining a clear and accurate understanding of what is wanted from a system and then systematically focussing design, implementation and testing on delivering that.

The approach is often illustrated as a ‘V diagram’ and fig. 1 indicates how this might look for a project to replace some railway signalling. In the figure, time runs from left to right and the vertical dimension indicates ‘granularity’ with activities relating to the whole system at the top and activities related to parts of the system at the bottom.

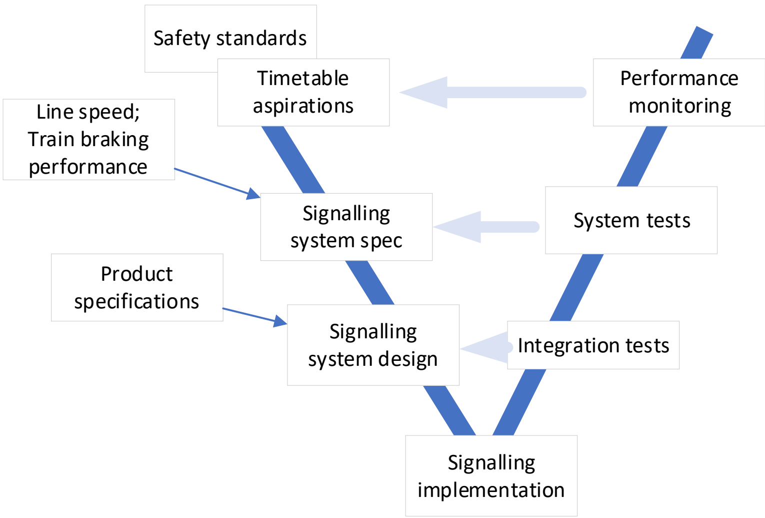

Fig. 1. A simplified V diagram for a signalling project

The activities on the left-hand side of the ‘V’ cover specification of the system and its components followed by design and implementation of the components. The activities on the right-hand side of the ‘V’ cover putting the components to work together and checking out the components and the system.

No system exists in a vacuum and the thin arrows coming in from the left indicate facts about the real world which need to be taken into account, if the system is to be successful.

If sufficient records are kept of the process, anyone designing or testing part of the system can establish how their work contributes to the overall objectives. One sometimes says that there is ‘line of sight’ to the objectives. Then, if the objectives or context, or our understanding of these things, should change, the V diagram provides a framework for efficiently and effectively changing the system in response.

In this paper the authors will explore how the V diagram and some of the ideas behind it might be used as a framework for efficiently and effectively changing the RSEI MSc programme rather than a technical railway system.

2 CURRENT PRACTICE

There has been a growing understanding of the importance of systems thinking as a requirement for successful engineers (McNaughton 2022) and the teaching of engineering has been moving away from reductionism and toward a more holistic perspective, with a need for engineers to have a broader knowledge of areas associated to their own and their interrelated systems. Thought has been given to teaching systems thinking both within engineering and other disciplines (Ravi et al. 2021) however the authors have found little consideration of how systems thinking could be used to improve teaching practice. If one accepts that systems thinking is an important skill for the engineer to develop, then thought also needs to be given to how a learning environment should be planned in order to facilitate its learning.

Of course, the principles underpinning the V diagram have already been partially adopted in further education. It is normal practice (Barkley and Major 2022) to define learning outcomes for an educational programme and then design the programme to meet these outcomes. Learning outcomes are based on what the learning institution and relevant advising bodies believe learners need to know. However, before embarking on or funding a period of education, students and their employers will normally have personal and business learning outcomes they hope to achieve. Successful programmes will be well aligned with these real needs.

In SE, one attempt to align industry needs with academic offerings has been 'The Graduate Reference Curriculum for Systems Engineering' (Pyster et al. 2012), a collaborative project designed to provide guidance on what providers of SE education should teach. It includes a V diagram with 'Program Objectives' at the top left. These adaptable objectives are focussed on student capability and employability. Similarly, Van Peppen and van der Ploeg (2000) established industry and learner objectives for a four-year master's programme in systems analysis, policy and analysis. In the UK, the Engineering Council publishes required learning outcomes for the Accreditation of Higher Education Programmes in engineering (Engineering Council 2020). These are frequently updated as the engineering industry undergoes change, such as changes in technologies. However, each of these documents, by necessity, serve multiple sectors with varying needs.

Some of our students take the MSc programme as part of the UK Rail and Rail Systems Principal Engineer degree apprenticeship. The standard for this apprenticeship (Institute for Apprenticeship and Technical Education 2018), which was written in consultation with the rail industry, specifies criteria for knowledge. skills and behaviours that an apprentice should have or exhibit upon successful completion of their apprenticeship. These criteria are about to undergo their first review, and with feedback from industry, it may be possible to identify the business benefits associated with meeting them.

However, although each of these sources provide elements for consideration, they sometimes contradict each other, and none provides a comprehensive and traceable set of business outcomes that are specific to our programme.

3 OUR APPROACH

As the authors have acknowledged, it is established practice to follow the constructive model, that is, to design educational material against defined learning outcomes and an understanding of what potential students want and then to assess whether these outcomes have been achieved. This could be represented as an application of the V diagram as illustrated in the boxes with a white background in fig. 2.

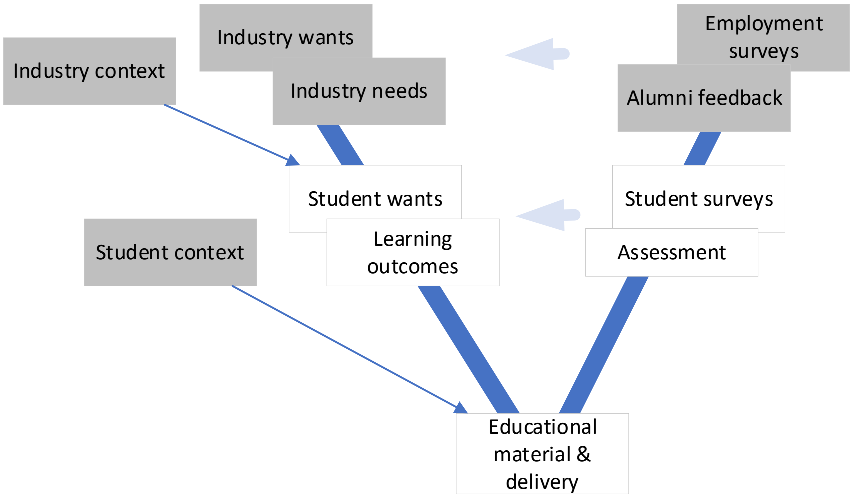

Fig.2. Current and extended practice in creating and improving an educational programme

We apply this process to the improvement of the RSEI programme, but our standard feedback arrangements provide us with feedback that is incomplete, potentially biased and occasionally conflicting. We are trying to improve the information available to us by extending it into the areas shown in grey. Our information gathering processes are not just passive feedback loops but are actively focussed on areas of interest. We are also using the V diagram as a framework for maintaining line of sight to the full set of feedback information in order to assemble a richer picture to support more balanced decision making.

4 KEEPING OUR UNDERSTANDING OF INDUSTRY WANTS AND NEEDS UP-TO-DATE

To contribute to industrial success, providers of relevant education need to help close 'skill gaps' - mismatches between the skills of available workers and the skills needs of employers (Department for Science 2021).

The RSEI MSc programme is designed to narrow the skills gap in the area of railway engineering. To understand this gap better the authors are carrying out research into the skill needs in this area in three different countries: the UK, the United Arab Emirates and Tanzania. To collect the skill expectations in these different cases, we are conducting online surveys and semi-structured interviews. We already convene a UK industry advisory board to collect industry feedback on the programme. We hope that these surveys and interviews will complement the industry advisory board by moving the discussion from the programme to the needs of industry and doing so for industry worldwide.

Only the literature review has been completed at the current stage. The literature review about the rail industry, its future, and railway education and training, shows that the skill expectations can mainly be classified in two categories: technical skills and soft skills. For the technical skills, the main gaps appear to be developing a holistic view of railway engineering and putting theoretical/technological knowledge into practice look like the main skill expectations from the industrial side. For the soft skills, the main gaps appear to be management and communication skills.

These findings are corroborated by other research into rail skills and skill expectations, most of which is of European origin. According to the European based research on skills education and training for the rail industry (European Union SKILLRAIL, SKILLFUL, and ASTONRAIL projects) (SKILLRAIL 2012), and UK Industrial Strategy – Rail Sector Skills Delivery Plan (GOV.UK 2018), there are also two main components of the skills gap in rail:

- Management and leadership skills.
- Being able to take account of new technologies and develop appropriate standards.

The RSEI MSc does cover management and leadership skills as well as innovation but, even though the findings of our ongoing research are very preliminary, the fact that these topics arise from multiple research activities is encouraging us to look again at them to see whether we should strengthen our teaching in these areas.

5 IMPROVING OUR UNDERSTANDING OF STUDENT CONTEXT AND WANTS

Students attending the RSEI MSc programme generally have rail industry experience. They will normally have specialised in one area of the rail industry and will be attending the programme to gain a wider knowledge of the industry as a whole. Around half of the cohort are students from the UK rail industry who by the end of the programme aim to have achieved promotion and/or engineering chartership. The rest of the cohort are international students, some of whom on completing the programme intend to return to home countries to further their careers, while others are looking for careers in the UK rail industry.

We also see students with a variety of educational backgrounds, including UK degrees, alternative qualifications such as a Higher National Diploma and overseas qualifications.

Therefore, we understand that our student cohort will have different wants, but also different needs in terms of support for them to achieve their learning goals. To be able to develop the programme and improve the support given, we need to have a better understanding of the students, and to obtain data on the optimum way to provide that support. It is worth considering that feedback obtained from students in a higher education setting can be prone to bias (Richardson 2005). This includes feedback collected from satisfaction surveys or other methods based on student opinion. Although, through surveys, anonymous data from large groups can be collected in a way that can be quantified, often this data lacks context which makes it difficult to interpret in terms of feedback for improvement (Desimone & Le Floch, 2004).

Other information such as the constant feedback loop between students and educators which comes from observing students' behaviour, questions, requests for help or even body language, can also be difficult to interpret. A few dominant students can give a skewed view and mean the view of the many is ignored, or data can be difficult to interpret in a non-biased way. Therefore, we need to look for methods of data collection, both quantitative and qualitative which remove subjective bias, and we need to consider how to use a number of different data collection methods to support findings.

Examining attainment results achieved in assessments across the taught modules within the program, has allowed us to identify areas where there are differences between certain groups of students and where support may be needed. In the rail program one obvious difference in attainment was between home and international students, with the most recent results demonstrating home students achieving 8% higher on average across the modules. When looking at data across several years, this gap appears to be growing. Our previous assumption that work experience in rail would give students an advantage in the program, was not supported by the data. English as a first language also appeared to have little effect on results. The largest single indicator of low results appeared to be that previous academic study had been undertaken overseas.

To understand why this gap is occurring, a study was undertaken to look at assignments in one module containing 56 students, of which 29 were international and 27 home students. Although, there were certain errors that were common to all students, by examining the written assignments it was possible to identify areas where each group needed support. For international students support was needed with understanding how UK academic questions are phrased and how to start answering them. Describing evidence for arguments and demonstrating critical thinking skills were also areas which needed support. Comparison between home and international students in the examination demonstrated that international students tended to achieve a higher percentage of marks from mathematics questions than home students which again helps to target support.

More detailed data focused on programme improvements has been collected through interviews with students. Issues such as the need for assistance with vocabulary and the use of recorded teaching materials for support have already been acted on. However, perhaps more interesting was the way in which interview responses could disagree strongly with other findings. Some such as interviewees claims that they watch recordings of lectures are easy to check using our software analytics, while insistences that there is little difference between assessment undertaken in home countries and in the UK are not backed by the attainment evidence or that obtained by the detailed study of assignment responses.

Finally, feedback has been obtained through semi-structured observations of group interactions. Although a powerful tool, little research has involved classroom observation (Agostinelli, 2021) and there is little consensus on how observation should be carried out. In this case observations took place over a period of ten hours during a week of group tasks. The aim was to record interactions between students and to look for patterns in behaviour, such as which students were more likely to be taking leadership roles, who was dominating speaking and who did what. In general, observations appeared to support findings from other studies. International students were more likely not to attend the group sessions, were less likely to speak in the group setting and appeared to complete a smaller percentage of the task, all issues which may lead to lower attainment in assignments at a later stage. Students were not directly questioned during the observation, however, several students wanted to talk about their experiences of group work which led to some interesting contrasts between what was observed and the perceptions of the students. For example, some home students were confident that they had tried to elicit discussion from international students, when observation suggested little contact. Also, a home student with industrial experience who had been observed to act as group leader and to organise other students, was convinced that they had undertaken no such role. One can observe what happens, but not what is in the mind of the student which demonstrates the need for multiple feedback loops.

This data that we have collected is already being used to inform changes in the coming year, with materials being developed for our Primer module to help students engage more effectively with assignments.

6 CONCLUSIONS

We have described how we are using the V diagram as a framework for improving the feedback available to us in order to inform improvements to the RSEI programme. We have sketched our research that we are carrying out into:

- what industry wants and needs from the type of education that we offer; and
- the variation in our student population and how we can take this into account to produce more consistent outcomes.

Our research is continuing but then so is the process of improving our MSc. We are committed to gradual but continuing improvement and, while we do not have definitive results yet, our interim findings are already providing us with richer input into the decisions that we are taking to improve our programme. Importantly, the results of our research are challenging some of our preconceptions which is an indication that our understanding is improved.

We are also using the V diagram as a framework for maintaining line of sight to the full set of feedback information in order to assemble a consolidated picture. Doing this brings into focus the conflicts between sources of feedback. Reconciling conflicting input is an unavoidable aspect of continual improvement. With richer input and the ‘line of sight’ afforded by the V diagram approach, we are confident that we can make better and more balanced decisions. Better and more balanced decisions should lead to a programme that is better aligned with the needs and wants of industry and students and the elimination of the effort required to undo undesirable changes.

We will complete our initial avenues of research, but we are already benefiting from the interim results and our research encourages that, if applied carefully, the ideas of SE can make a positive difference to achieve a better educational experience in engineering disciplines.

ABSTRACT

In the current age, digital advancements have shaped the educational landscape by providing numerous possibilities for a fast and on-demand influx of information for students. This brings an additional difficulty for course designers in how to incorporate such technologies in teaching in an optimal way. Key examples are educational videos, which are especially relevant now due to the increase in accessibility of pre-made videos and recording technology since the pandemic. This puts post-pandemic teaching in the new but revolutionary position to complement in-person teaching with videos.

In this study, we examine the effect of videos combined with in-person teaching in a mathematics master course in motivation and grades. This experiment is specifically insightful due to our course consisting of three different topics (A,B,C). In Year 1 (control group), the course was taught traditionally. In Year 2 (experimental group), we provided additional video lectures on (A), while keeping (B) and (C) as before. We compare assessment and survey results between and within years.

Videos did not increase the students' motivation for the topic (Fisher exact test p = 0.06182). The intervention did not improve the midterm or final exam grades on (A) between years. Students who watched videos did not score significantly better on their assignments (2MWUt p = 0.275) nor on their exams (2MWUt p = 0.745) than students who did not watch the videos. However, a positive effect size was observed between years, while the intervention led to a negative effect size within the same year.

1 INTRODUCTION

Technology is fully integrated into everyday life, which has had a positive effect on students' internet and computer skills and their attitude towards digital educational resources from a young age (Kuhlemeier and Hemker 2007) and (Sharples et al. 2007). This presents an opportunity in transferring this experience in a classroom environment. Specifically for learning mathematics at university, using *online videos* has been shown to have advantages. The topic of video integration into in-person lectures is especially relevant in a post-pandemic teaching environment, where copious amounts of video material and recording hardware, used during the pandemic, are available. Teaching staff both acknowledges the importance of in-person teaching and recognises the benefits of videos and recordings (Robson, Gardner, Dommett 2022). It is therefore of great interest to investigate if the combination of in-person teaching and video material can elevate teaching in a post-pandemic time.

Benefits of videos include flexibility of scheduling and pace, and avoidance of long lectures. In contrast, the main perceived advantages of lectures are the ability to engage in group tasks, to ask questions, and to learn 'gradually' (Howard, Meehan, Parnell 2018). The same study also shows that students in clusters with high lecture attendance achieve, on average, higher marks in the module. Therefore, videos provide a useful resource, which should be used in this context only and in conjunction with lectures. Further studies focus on the relationship between learning and time spent on lectures and/or videos. Findings show that students use videos as either a complement to or substitute for the lecture, and time spent using either or both resources has a significant impact on learning (Meehan and McCallig 2019).

In this work, we measure the effect of video-integrated education in combination with in-person teaching. The goal of this work is to answer the following questions:

1. Does the addition of videos to in-person teaching improve the students' grades?
2. Does the addition of videos to in-person teaching improve the students' engagement with the course?

In order to give a statistically sound answer to these questions, we track the data of two years of the same master course in mathematics at the Eindhoven University of Technology in the Netherlands. In the first year, the course was given traditionally, while in the following year videos were included. The first year serves as a benchmarking iteration where typical course standards are maintained. This is followed by an experimental iteration in the following year where, in addition to the standard practice of the course, video lectures are *partly* provided, i.e. *only* for a specific part of the course. This creates two natural control groups. Within a year, it allows us to compare the effect of the videos by comparing grades between the topic where videos were provided for or not; between years, grades on the other topics help check for heterogeneity. We refer to Section 2.1 for a detailed overview of the experimental setup.

We use the answers to the questions above to formulate concrete advice if additional videos have an inherent added value to in-person teaching for students. Based on this advice, one may include videos in their course if the expected benefits justify the investment of time and resources. Note that these conclusions are in the specific context of a specialized and rather challenging first year master course in mathematics.

2 METHODOLOGY

2.1 Experimental setup

The experiment takes place in an established master course in mathematics in the Netherlands. The course comprises three topics in stochastics: renewal processes (A), branching processes (B), and Brownian motion (C), which are taught sequentially in three modules in this order. The three topics are sufficiently independent; i.e. for any module there are no required prerequisites from a previous module. Throughout the course, basic probability topics (D) appear as needed. The design involves a two-hour, on-campus lecture, followed by a two-hour guided self-study, twice per week for eight weeks. Examination weeks are scheduled afterwards. The material offered to students is lecture notes, one single book covering all topics, instruction sets, sketches of solutions to the instruction exercises, and practice exam sets for the final examination.

To assess students, at the end of each module a midterm examination is given in the form of take-home problems that can be solved in pairs or alone. At the end of the course, students take a three-hour individual final exam where all topics are tested. The midterms and the final exam are graded on a 0–10 scale. The three midterms count each for 10% of the final grade and the final exam counts for 70% of the final grade. A final grade of at least 5.50 is needed to pass the course.

The course was taught with the same setup, teaching staff, and material (with the exception being the inclusion of the videos required to perform this experiment) between two years. In Year 1, the course was given traditionally, i.e. with the setup described above. In Year 2, videos were recorded by the lecturer on (A) and offered to all students at the beginning of the course. Students could optionally engage with the videos throughout the whole course and examination period, i.e. for a total of 10 weeks.

The videos used in Year 2 consisted of six mini-lectures: three informative presentations on theoretical topics and three on applications. For both parts, one video was in the scope of (A) and handled in class and two were new material. The videos were put online and it was indicated if a video was on theory or on an application. The differentiation between theory and applications as well as known and new subjects could have allowed for a determination of whether students are seeking help when engaging with a video or are intrinsically interested to learn more about (A). However, this differentiation, together with the fact that the material was optional, reduced the relevant sample size per video, thus not allowing for meaningful statistical analysis.

By providing videos only for one out of three topics, a meaningful comparison can be made between the performance of the students in two consecutive years on the topics with and without videos. Students were offered the new video material but were not obliged to follow it. All students were asked in a questionnaire if they engaged with the videos or not. This allowed for additional comparisons within (A) in Year 2.

While Year 2 took place during the Covid-19 pandemic, this specific course was chosen by the Programme Director for on-campus education allowing for a fair comparison between the two years. In addition to keeping all setup, material, and staff identical, care was taken to avoid confounding factors by design. For example, each midterm per topic and each topic in the final exam was assessed by the same person both years. The number of registered students was 73 and 74 in the two years.

2.2 Data and reliability

We use anonymised data of students of Years 1 and 2 contained in three datasets. Dataset 1 consists of midterm grades of (A,B,C) and exam grades per topic (A,B,C,D) and year. The grades on (A) between years may attest for the effect of videos, while the grades on (B,C,D) give an indication of difference between the two years as no changes in education were made for these topics, thereby assessing the effect of possible confounding factors due to the different cohorts.

To perform statistical tests based on Dataset 1, we ensure that student groups from Years 1 and 2 are independent. Therefore, we remove students that were present in both years to avoid dependencies. For a fair comparison, we also remove students in Year 1 if they had taken the course the previous year, as they had prior knowledge. However, this introduces a bias toward higher grades in Year 1 and therefore students that scored lower than a 5 on their exams in Year 2 are removed as well. Therefore, the data is limited to the groups of students from either year that took the course for the first time *and* passed, making these groups comparable and independent. The resulting sample sizes in each year are again similar: 45 and 42 students.

As is usual with test or survey data, we test the reliability of the midterm, exam, and survey questions in order to identify and remove questions that are not discriminatory. In Dataset 1, we measure the overall reliability of the midterm and final exam with the Cronbach alpha coefficient (Cronbach 1951). We then look at the average score of each question and its correlation with the other questions in the exam. If the correlation of the total score on the question is below 0.15 or above 0.85 or the correlation with the other questions is below 0.15, the question is removed from the analysis. Data per question was not available for the midterm on (B) and (C) in Year 1 and thus all questions of these midterms are included in the analysis.

Dataset 2 consists of survey results of students (on a voluntary basis) in Year 2. The first part of the survey consisted of basic questions: which of the six video lectures (if any) did they watch; which was their favourite; what was the number of hours they spent on the course per module. The latter information is used to investigate if students that watched at least one video are statistically different than those who did not watch the videos (e.g., harder or less hard working). This is a key measure to account for the possible occurrence of *selection bias*, since watching the videos was voluntary. Surveys were performed at the end of each module rather than only at the end of the course, thus allowing students to have a fresh (and hopefully accurate) estimation of the effort they expended. The second part of the survey asked students two main questions on what the effect of the videos was for them:

1. If it made (A) more interesting for them;
2. If it made the course as a whole more interesting for them.

On each question the students could respond with “yes”, “somewhat” and “no”. This information is used to test the motivation for (A) and for the course as a whole of students between those that watched at least one video and those who did not.

Dataset 3 consists of Student Evaluation of Teaching (SET) reports for the two years. They were used to test whether students in Year 2 spent more time learning.

2.3 Statistical methods

To answer the first main question on whether the video lectures had an effect on grades, we examine the following hypotheses:

H_0: The probability of a uniformly sampled grade from Year 1 being larger / smaller than a uniformly sampled grade from Year 2 is ½.
H_1: The probability of a uniformly sampled grade from Year 1 being larger / smaller than a uniformly sampled grade from Year 2 is not ½.

For this, we use the grades in Years 1 and 2 (Dataset 1) and employ the two-sided Mann-Witney U test (2MWU) (Mann and Whitney 1947). This non-parametric test investigates the locations of two independent samples by using ranks and is suitable for small-sample ordinal data, as is the case when examining grades. We also report the median and interquartile range (IQR) of the grades of the two years separately.

To answer the second main question on whether the video lectures had an effect on the engagement of students with the course, after testing for differences in engagement between years, we examine the following hypotheses:

H_0: The results between groups in Year 2 are from the same distribution.
H_1: The results between groups in Year 2 are not from the same distribution.

For the comparison of survey results within Year 2 (Dataset 2), we use the Fisher’s exact test (Sprent 2011). It is suitable for categorical survey data, as we have, where students can answer either “yes”, “somewhat”, or “no”, from independent groups of students that did not watch the videos and the group of students that watched at least one video. The statistical tests are performed on a significance level of $\alpha = 0.05$ that is adjusted to correct for multiple testing where needed: when the final exam is considered both as a whole, and as a set of subparts comprising the topics (Bonferroni correction, $\alpha = 0.025$). We do not correct for multiple testing when considering midterms and the final on the same topic as we believe they can be seen as independent due to the different modalities (take-home/in-class, group/individual, with/without resources).

In all relevant cases, in addition to statistical significance, we also report the effect sizes. Unless the impact of the intervention is huge, a study of this size is unlikely to get a statistically significant result. Thus, reporting the effect adds nuance to the results. The effect size is a standardized, scale-free measure of the relative size of the effect of an intervention. It is particularly useful for quantifying effects measured on arbitrary scales. In education, if it could be shown that making a small and inexpensive change would raise academic achievement by an effect size of even as little as 0.1, then this could be a very significant improvement, particularly if the improvement applied uniformly to all students, and even more so if the effect were cumulative over time; see also (Coe 2002) for a discussion.

3 RESULTS

3.1 Between years

The analysis of the SET results between years shows that students spent on average the same amount of time on the graded component of each module, with means 8.2915 hours in Year 1 and 8.2995 hours in Year 2 for module (A), and on the whole course.

Dataset 3 is gathered by the university and reported on an aggregate level. We thus cannot distinguish between students who repeated the course and those who did not.

In Table 1, we compare the grades of Year 1 to the grades of Year 2 in Dataset 1. For the midterms, we observe a significant difference in grades only for midterm (C), while the other midterm grades did not differ significantly between years. This may indicate that Year 2 had stronger students. This is, however, in strong contrast with final exam grades on (C) and (D), where students scored significantly lower in Year 2. It is notable that the effect of the intervention is positive for all midterms and the intervention topic (A) in the final exam, but negative for all other topics in the final exam.

Table 1: Summary statistics of the grades per topic for the midterms (A,B,C) and final exams (A,B,C,D) in Years 1 and 2. Non-discriminatory questions were removed when possible. The p-value corresponds to the 2MWU test between Years 1 and 2. Boldfaced values indicate that the null hypothesis was rejected under a significance level $\alpha = 0.05$ (0.025 where a correction for multiple testing was needed). The Cliff's Delta effect size and 95% confidence interval are given.*

Between years	**Year 1 (control)**			**Year 2 (intervention)**			**p-value**	**Effect size**	**95% CI of the effect size**
	n	**Median**	**IQR**	**n**	**Median**	**IQR**			
Midterm (A)	30	8.15	[7.18,8.88]	27	8.45	[7.70,9.50]	0.149	0.217	[-0.087,0.483]
Midterm (B)	30	9.00	[8.00,9.75]	27	9.10	[8.80,9.40]	0.445	0.118	[-0.199,0.412]
Midterm (C)	30	7.50	[7.00,8.50]	27	8.70	[8.06,9.71]	**<0.001**	**0.546**	[0.260,0.744]
Final (A)	45	4.00	[1.00,7.00]	42	5.38	[4.75,6.25]	0.033*	0.265	[0.003,0.493]
Final (B)	45	7.60	[6.00,9.60]	42	7.5	[6.56,8.30]	0.520*	-0.080	[-0.318,0.167]
Final (C)	45	8.67	[6.89,9.78]	42	7.29	[6.82,8.61]	**0.007***	**-0.338**	[-0.522,-0.123]
Final (D)	45	5.00	[3.33,7.33]	42	3.33	[2.08,4.33]	**0.011***	**-0.318**	[-0.524,-0.076]
Final total	45	7.02	[6.21,7.84]	42	6.61	[5.45,7.19]	0.082*	-0.217	[-0.430,0.018]

3.2 Within Year 2

Next, we compare students within Year 2, separated in two groups: students who watched at least one video and those who did not watch any videos. We examine the results on the two main questions of the survey. The results are presented in Tables 2 and 3. To test whether the number of students reporting an increased motivation for (A), we perform a Fisher exact test. There is not enough evidence to reject the null hypothesis of equal distribution (p-value = 0.06182). To analyse whether videos increased motivation of the course as a whole, we perform the same test on the frequencies reported in Table 3. The outcomes between the two groups differ (p-value = **0.0122**). Thus, we conclude that students feel that videos increased their motivation.

Table 2: Survey results on the question: "Do you feel that the videos made renewal processes more interesting for you? Or in lack of interest, did you appreciate the topic more?"

Increase motivation for (A)	**Yes**	**Somewhat**	**No**	**Total**
Watched a video	5	9	5	19
Did not watch a video	0	4	7	11
Total	5	13	12	30

Table 3: Survey result on the question: "Do you feel that the videos made the course any more interesting? Or do you feel that the videos were of any added value to the course?"

Increase motivation course	**Yes**	**Somewhat**	**No**	**Total**
Watched a video	9	6	4	19
Did not watch a video	0	6	6	12
Total	9	12	10	31

We next consider if students that watched the videos are significantly more engaged with the course. This is tested based on the number of hours students report to have worked on the course per topic. It is important to note that these numbers are self-reported by students. For all samples (i.e. per topic and group) the Shapiro-Wilk test does not reject the hypothesis that the hours reported follow a normal distribution (p-values ranging from 0.092 to 0.925). An F-test does not reject the hypothesis that the samples have the same variance. We thus assume normality of the data and employ a two-sided *t*-test with equal variances to compare the effort in hours between groups. The results are presented in Table 4.

Table 4: Summary statistics of the number of hours students spent studying in total per topic. Students are split into groups that did not watch the videos and that indicated to have watched at least one video. The p-value reported is based on a two-sided t-test with equal variances. The Cohen's d effect size with Hedges g correction is given.

Within Year 2	Did not watch any videos (control)			Watched a video (intervention)			p-value	Effect size	95% CI of the effect size
	n	Mean	S.d.	n	Mean	S.d.			
Topic (A)	27	30.15	12.04	19	37.42	11.90	**0.049**	0.596	[-0.009,1.202]
Topic (B)	27	24.89	11.42	19	27.58	11.49	0.437	0.231	[-0.364,0.826]
Topic (C)	27	25.48	11.47	19	31.26	13.54	0.125	0.460	[-0.141,1.061]
Total	27	80.52	32.07	19	96.26	33.73	0.116	0.472	[-0.129,1.074]

Students who watched a video spent on average more time on (A). The difference in the mean is roughly equal to the time required to watch all videos, which is a possible explanation. All other differences in time spent were not statistically significant.

We also consider if the group that watched the videos scored significantly better on their midterm and final exams. As students were allowed to make their midterms in pairs, we test if the pairs in which *at least one student* watched a video performed better on their midterms than pairs in which *none of the students* watched a video. Additionally, we present the exam grades of students in Year 2 for students that did not watch any of the videos and for students that watched at least one video.

Table 5: Summary statistics of results of student pairs per topic in Year 2. All pairs are clustered into two groups: one in which neither student watched a video and one in which at least one student watched at least one video. We report the p-value of the 2MWU test between groups. Boldfaced values indicate that the null hypothesis is rejected under a significance level $\alpha = 0.05$. (0.025 where a correction for multiple testing is needed). The Cliff's Delta non-parametric effect size and its 95% confidence interval are also given.*

Within Year 2	None watched a video (control)			At least one student watched a video (intervention)			p-value	Effect size	95% CI of the effect size
	n	Median	IQR	n	Median	IQR			
Midterm (A)	11	8.60	[7.78,9.65]	16	7.70	[6.85,8.95]	0.275	-0.325	[-0.683,0.159]
Midterm (B)	11	9.00	[8.73,9.38]	16	9.10	[7.95,9.25]	0.107	-0.149	[-0.524,0.273]
Midterm (C)	11	9.35	[8.39,9.79]	16	8.35	[7.75,8.85]	**0.048**	-0.383	[-0.723,0.106]
Final (A)	22	5.38	[3.91,6.19]	16	5.38	[3.97,6.06]	0.745*	-0.065	[-0.421,0.307]
Final (B)	22	7.40	[5.85,8.23]	16	7.00	[5.88,7.85]	0.679*	-0.082	[-0.430,0.286]
Final (C)	22	7.41	[4.64,8.61]	16	7.09	[6.07,8.39]	0.801*	-0.051	[-0.403,0.313]
Final (D)	22	2.10	[1.00,2.55]	16	1.90	[1.00,2.70]	0.413*	0.045	[-0.331,0.410]
Final total	22	6.12	[4.97,6.58]	16	6.04	[4.71,6.71]	0.859*	-0.028	[-0.389,0.340]

We observe only a significant difference in grades on midterm (C), where the groups that watched the videos scored significantly lower. Therefore, there is no significant change in grades of midterms on (A) or on the exam on (A). Note that in all cases except for topic (D), the effect size of the videos on the grades is negative.

4 CONCLUSION

There no statistically significant improvement in grades between Years 1 and 2. On topic (A) of the final exam, grades seem to be improved, but statistical significance is not reached after Bonferroni correction (p-value=0.033). On the other hand, the effect size is positive (0.265, 95%CI=[0.003, 0.493]). Also on midterm (A), the effect size is positive (0.217, 95%CI=[-0.087, 0.483]), although the result is not statistically significant (p-value=0.149).

As evidenced by the lack of significant unilateral changes in grades for (B,C) between years, we find that one cohort of students was not significantly performing better or worse than the other. Only on the midterm (C), we observed an increase in grades (Y1 7.50 [7.00, 8.50], Y2 8.70 [8.06, 9.71], p-value<0.001), but the results on the final (B,C,D) have negative effect sizes and reach statistical significance for (C,D).

Based on Table 5, we also do not observe a significant difference in grades between students that watched at least one video and students that did not watch any videos within Year 2. This indicates that selection bias did not play a significant effect in the analysis. Also, by the removal of non-discriminatory questions, the most important confounding factors in this analysis have been accounted for. Therefore, we find only a mild marginal effect of videos improving students' grades.

We find some evidence of improvement in motivation in the group of students who watched the videos. Concretely, there is no significant improvement in motivation for (A) based on Table 2 but there is a significant improvement in motivation for the course as a whole based on Table 3.

Moreover, Table 4 shows that students who watched the videos did not engage more in the course in terms of hours spent per topic. As the group that watched at least one video did not significantly work harder for the course than those that did not, according to Table 4, we find that the former group was not engaged with the course more than the latter in terms of hours spent on the course. This outcome shows that the group that chose to watch the videos are not inherently working harder, if measured purely by the amount of time they spend on the course. Therefore, the effect of videos on motivation is marginal, which concludes our second research question. On the other hand, it could be that students already inclined to the subject (and that need to spend less time to grasp the compulsory material), also engage with the videos. However, this is not visible in the grades.

Combining these results implies that the effect of including video material in combination with in-person lectures is modest. Our sample size was limited, especially when considering the complex framework that is analysed and the small effect sizes at hand. This may have prevented us from finding statistically significant results. For similar courses, it is therefore advisable to critically assess if the time and effort for the creation and integration of video is justifiable when the benefits are expected to be limited. On the other hand, the analysis shows no significant negative effect on students' grades or motivation. If videos are readily available and easily to implement, we find no evidence against including them as optional material; however, expectations should be managed accordingly.

5 DISCUSSION

When interpreting the results, it is important to keep in mind that the outcomes are based on two years of a specific master course in mathematics in the Netherlands. Courses of a different level or other university subjects may be better or worse suited for video integration. Additionally, students of different age, level, or field of study may respond differently to videos. The videos were made by the lecturer, with the input of students who took the course in the past years, in order to calibrate the potential interest students may have in the material. Professionally directed videos, or of a different format (in duration or media used), could have a different effect on the engagement of students. Finally, while the course is given in English and open to students from other countries, a large part of the students is Dutch. Different cultures may respond differently to videos.

While we carefully accounted for different confounding factors, it is possible some inevitable and hard to control effects were present on the background. An example is the pandemic that was making its uprise during Year 1, whereas the first pandemic wave was on its decrease during Year 2. Although both years provided on-campus teaching, the pandemic was in very different stages between years. This may have influenced the experiment. For example, students may have been more experienced with video lectures in Year 2 or may have had intrinsic variations in focus and motivation for coursework after the extended measures the pandemic required. As this course was selected for on-campus education, this may have created a welcome respite from isolation, which could be a confounding factor for engagement.

Another potential confounding factor relates to the content of the midterms and exams. They must be distinct between years. We accounted for discrepancies by removing non-discriminatory questions and keeping the graders the same between years. The assessments were designed by the same person. These measures are however not a perfect technique as some differences in level may still be present. Similarly, while the teaching staff did not change between midterms, it is possible that the quality of lectures or grading between years differed. We believe that these effects are mild as Table 1 does not show a convincing consistent difference in results between years.

Future years can expand upon the analysis here. First, the selection bias can be eliminated by making the videos and survey mandatory. However, it is not straightforward how to properly implement this in practice, i.e., how to reward or penalise students who did or did not watch the videos respectively. If future studies increase the sample size of students, it can additionally be tested which type of videos (i.e., on theory or applications) students prefer and if one version typically results in higher grades or motivation. This would add an additional research question to what *kind* of videos are optimal to use.

Future research may also examine the effect of other properties such as video length, quality, and presenter. If future studies allow us to follow students for a longer time, we can test the long-term effects of videos on students. This adds an additional research question if videos improve the *learning retention* of students in practice. While these questions are of great interest, they are left for future investigation.

Overall, our research shows no statistical significant results, but reveals modest effects of this intervention. In closing, it is important to highlight and emphasize the critical significance of not merely assuming the effectiveness of technological interventions in education. Instead, it is crucial to encourage rigorous educational research that enables more thoughtful and informed assessments of similar integrations.

ABSTRACT

In a digitalized world, most processes can be formalised, measured and described mathematically. The use of analytical methods to optimise such models and decisions constitutes operational research (OR), developing new methods for a specific problem and analysing them are part of discrete optimisation (DO). However, there is limited research on OR and application driven DO in higher education. Furthermore, neither is well integrated into engineering education research.

In this work, we present a case study of an interdisciplinary Master's course on heuristic methods in the context of OR and DO. We discuss to what extent well-established approaches from engineering education practice, such as Problem-Based Learning, are applicable. Furthermore, we introduce two practical cases and argue that due to its application-oriented nature, OR and DO specifically stimulate independent student work.

Results from evaluations, minute papers and student coursework indicate that the teaching approach successfully contributed to students' achievement of the intended learning outcomes.

To further foster discussion, we not only provide the lecture notes publicly, but also all tutorial and project case data to instructors upon request under a CC BY-NC license.

1 INTRODUCTION

In a digitalized world, most processes as in logistics, health care, education or production can be formalised, measured and described mathematically. The use of analytical methods to optimise such models and decisions constitutes operational research (OR). Developing new methods for specific problems from these fields and analysing them form a rich source of novel discrete optimisation (DO) problems. This designation is not clear cut: analytics, systems engineering, industrial engineering, operations management, management science, discrete and combinatorial optimisation, algorithms and complexity, and operational (operations) research represent closely linked fields that all deal with the use and development of methods to describe, predict and improve processes.

Many problems can be solved exactly within reasonable time, even for large instances. However, there are also numerous problems, e.g. (capacitated) vehicle routing, partitioning or even general integer programming, where finding an exact solution in reasonable time is, as of today, impossible (Sleegers et al. 2020; Peter Cheeseman, Bob Kanefsky, and William M. Taylor 1991). The alternative here is to use heuristics, i.e. algorithms that generate acceptable outcomes in a reasonable time. Today, many real-world problems such as scheduling, assignment, routing and/or logistics require heuristic approaches to solve large instances without a special structure (Gendreau and Potvin 2019; Martí, Pardalos, and Resende 2018).

While there is a lively debate about teaching classical mathematics to engineering students, published research on teaching operational research and discrete optimisation in higher education is sparse to the point of being non-existent. Neither the European Society for Operations Research (EURO) nor various national association have a working group or designated teaching streams as a regular part of their program and conferences. We found two reviews on teaching operations management in Spain, which point out the lack/absence of research into teaching methods (cf. Marin-Garcia 2018; Carmen Medina-López, Alfalla-Luque, and Marin-Garcia 2011). The more recent publication by Marin-Garcia (2018, 612) analyses the research focuses of 25 publications in Spain. He points out that a majority of publications have a research focus (unsuccessfully) aimed at finding a "silver bullet" teaching approach that works equally well for any student and context.

As such, what constitutes appropriate methodology to teach OR largely remains an open question. That is specifically relevant because, while OR draws deeply on discrete mathematics and computer science, it is fundamentally different from much of engineering mathematics teaching in that it does not provide fundamentals for other engineering classes but represents a skillset in itself.

In this work, we present a case study of an interdisciplinary Master's course on heuristic methods in the context of OR. We discuss to what extent well-established approaches from engineering education practice, such as Problem-based Learning (PBL), are applicable. Furthermore, we introduce two project cases and make a point that due to its application-oriented nature, OR specifically stimulates independent student work. To further foster discussion, we not only make the lecture notes are publicly available[2], but also provide all tutorial and project case data available to instructors upon request under a CC BY-NC license.

The paper is organized as follows: In Section 2, we introduce the course design, i.e. the learning outcomes and teaching contents (2.1), the structure of the course (2.2). This is then discussed in the context of active and problem-based learning (2.3). In Section 3, the above is evaluated based on the previously described data. Finally, Section 4 gives a summary and outlines both lessons learned and potential future improvements.

2 COURSE DESIGN

The context of this work is the interdisciplinary Master's course called "Mathematical Heuristics for Discrete Optimisation" (MaHeu) at RWTH Aachen University. The course consists of three main parts: a lecture, which takes place twice a week, a weekly tutorial session, and a practice case that students work on in teams. These three parts are interlinked. The lecture follows a PBL approach, where working sessions and practical problems are used to introduce students to relevant methodology, while relevant software is introduced and practiced in the tutorial. Both serve to prepare students to independently work on the case. In dealing with the case, the students work with data, implement their own algorithms, evaluate these computationally and discuss real-world applicability.

Grading is jointly based on a team grade for the project and individual oral exams. Upon successful participation, students are awarded 9 ETCS. Most participants take MaHeu as a compulsory elective subject in mathematics at either the Bachelor's or Master's level, or as part of their computer science Master's degree. The number of students finishing the course was 12 in 2019, 13 in 2020, 8 in 2021, 16 in 2022 and 21 in 2023.

2.1 Learning outcomes and teaching content

Following constructive alignment, intended learning outcomes (LOs) were formulated at course level (Biggs 1996). First, after successful participation, students *know major principles of both heuristics, metaheuristics and approximation algorithms.* Second, they *evaluate the necessity and suitability of using heuristics to solve given DO/OR problems.* Third, *they apply existing heuristics to established DO/OR problems*. Fourth and fifth, students *model novel, complex real-world problems mathematically* and they *modify and implement existing heuristics to solve those*.

---

[2] https://combi.rwth-aachen.de/teaching/resources/MaHeu_LectureNotes.pdf

Sixth and finally, they *evaluate the suitability of such methods using both proofs and computational experiments*.

The first three LOs are addressed in both lecture and tutorial, and assessed in an oral exam at the end of term, together with the ability to perform mathematical proofs as asked for in the final LO. As part of the case, the other LOs are developed, and assessed in a presentation and a written report.

Note that single solution-based heuristics are a focus of this specific course, and population-based approaches, e.g. genetic algorithms are not covered in detail. However, an overview is given at the beginning of the term, which includes the optimisation cycle as standard approach to tackle optimisation problems the classification of algorithms and the main components of every heuristic. Then the difference between heuristics and approximation algorithms is discussed and the “no free lunch” theorem is introduced. Based on this, several fundamental paradigms for heuristics are covered in the following sections, as given in Table 1:

Table 1. Mathematical heuristics teaching contents.

Concept	Theory	Problems
Greedy	Different types of approximation ratios, series-parallel graphs	Minimum cost flow, set cover, k-center, Travelling Salesperson (TSP,) Independent sets and matroids
Local Search	Neighbourhoods	Machine scheduling, (Minimum degree) Spanning trees, k-median, Spanning trees with many leaves
Randomisation	Rounding, expected runtime, random approximation, Greedy randomized adaptive search procedure (GRASP)	Max-Satisfiability Problem (Max-SAT), Max Cut
Very Large-Scale Neighbourhood Search	Compound Swaps, DynaSearch, Eject & Reinsert, Lin-Kernighan	Machine Scheduling, TSP, Partitioning, Capacitated Minimum Spanning Trees
Simulated Annealing	Asymptotic Convergence	TSP

There is also a special section in the lecture on evaluation of algorithms that contains both evaluation techniques and practical content for doing computational studies.

2.2 Course structure

As discussed at the beginning of the section, the course consists of three elements: A lecture, a tutorial and a case. These are now covered in more detail.

Lectures take place twice a week. Small algorithm design and programming exercises are interspersed throughout the lecture, e.g. the problem of analysing the practical performance of algorithms and their comparison are introduced on the example of the traveling salesperson problem. The students work in small groups to discuss what questions should be answered by the computational study, and then perform an analysis on a given set of data via R[3] and compare their findings.

The lecture notes are provided digitally via RWTH's Moodle learning management system. Videos of past years are also uploaded and TikZ[4] based animations of all algorithms and concepts covered in the lecture are provided in an extra extension of the lecture notes.

The tutorial sessions take place weekly. Each week students are given a sheet with exercises to solve at home and then present next week. During the week, students send their solutions to an instructor who provides feedback. Some tutorial sessions specifically focus programming with domain specific software. This includes the statistics software R and the modelling language AMPL[5], together with CPLEX[6]/gurobi[7] as solvers. Those software packages constitute standard tools in optimisation/analytics that also offer free academic licenses. Students need to actively participate in the tutorial to gain admission to the exam. Here, active participation consists of presenting one or several solutions, with the number varying based on the number of participants.

Working on the case begins a month after the lecture/tutorial started and goes on for two months. Student groups work together in teams of four to six. At the end, students have to hold a final presentation and hand in a team report of up five pages.

For 2019-2022 the project was on the optimal wiring of heliostats for solar power towers based on previous research work of our group (see Richter et al. 2019). This year we updated the case to an operative surgery scheduling problem. Since real-world surgery data is subject to strict data protection in the European Union, we based the case on publicly available research data (see Leeftink and Hans 2018). Both projects were chosen because they address relevant real-world issues and they allow for the usage of simple heuristics to construct an initial feasible solution. The latter means that every group will be able to present some solution and students can differentiate themselves in terms of solution quality. Moreover, both cases are based on past (heliostats) and ongoing research of our group (surgery scheduling).

Note that the course itself is held in either German or English, depending on student preferences, and lecture notes, case description and tutorial exercises are in English.

2.3 Active and Problem-Based Learning

The course structure is specifically built on established educational practice in the context of engineering education. Active learning has shown to engage students in

the learning process and thus positively affect the acquisition of intended learning outcomes (Freeman et al. 2014; Prince and Felder 2006). Specifically, the combination of activity and variety has been shown to increase student interest, improve attendance and increase learning (Felder and Brent 2016; Prince 2004). This was used as a motivation to change the lecture content away from a standard frontal format towards a more active and student-centred design, and to ensure that the course itself is varied in terms of formats for students.

PBL is a teaching method in the context of active learning. The problem itself is used as context and motivation for learning (Prince 2004; Edström and Kolmos 2014). This is mirrored in Table 1, where each teaching content is interlinked with one or several problems. In each teaching block, these problems are used to motivate the corresponding solution techniques. Furthermore, students experiment on different problems and solution approaches themselves.

Note that allowing students a combination of experimentation, instrumentation, troubleshooting, modelling, self-directed and creative thinking, instead of a fixed sequence of tasks to fulfil, is also an important factor that contribute to the success of practical lab exercises (Felder and Brent 2016). We decided to support this through the real-world case. Specifically, the project description calls for students not just to identify the/one optimal solution but to test out different approaches and compare them based on knowledge acquired during the course.

3 EVALUATIONS

Course evaluation takes place through student coursework, weekly minute feedbacks and a final evaluation. This work is based on five years of teaching, i.e. the spring terms of 2019–2023. In 2020 and 2021, due to the COVID-19 pandemic, lecture and tutorial were held remotely.

All final evaluations are part of RWTH's quality management system. They consist of a range of items on a 5-point Likert scale ranging from 1 (very good) to 5 (very bad), and two fields for further comments, i.e. notable positive elements and suggestions for improvements. As the course and evaluation were held in German, all comments were translated to English.

Between five and nine students participated in the evaluations. Across all years, the overall grades were between 1 and 2 and no course nor instructor received an evaluation worse than 2 (good). In 2019 and 2020, students repeatedly remarked a lack of summaries as part of the lecture and marked down the corresponding item, those were subsequently added at the end of lecture content. During the COVID-19 pandemic, i.e. the spring terms of 2020 and 2021, multiple students remarked upon changed circumstances due to remote learning. Whereas some students mentioned the advantages of increased flexibility in learning and time saved due to not having to travel to university, others criticised the lack of personal interaction with both peers and instructors. In the exercise, the instructor offered an open digital meet-and-greet session before each exercise, which was received very well by students, although the fundamental criticism remained.

Across all years, students rated the module as providing an appropriate level of challenge and workload. As one student put it:

"As computer science student […] this was the first mathematics module that wasn't too hard because I lacked prerequisites […] nor to easy […] but demanding in a good way due to the complexity of the content. […]"

Students also remarked positively on both the course teaching: “The interactive nature of the lecture gets you to think for yourself an keeps you attentive.”, and the structure of the whole module: “The structure of the module with exercise, project work and oral exam is a welcome change.”

The weekly minute-feedbacks were divided into two parts: lessons learned, and questions suggestions for improvement. Students could voluntarily fill out the feedbacks. In general, students were diligent in filling out the feedbacks, specifically when it came to listing the topics covered in the last session. Questions frequently focused on formal definitions, e.g. “What precisely is the difference between general and problem specific heuristic?” or “How is an independence oracle defined formally?”, or they focused on follow-up questions regarding extensions of specific algorithms or e.g., general procedures for derandomization. However, most answers simply noted that students were happy with the course and enjoyed both teaching and content.

Generally, students’ reports were well crafted and their solutions made use of a range of different approaches. Frequently, either TSP or MST based heuristics were used as the starting point for the heliostat problem, with local search used for intensification. Similarly, GRASP procedures were frequently employed. Many groups also sliced the heliostat area into parts, making use its geometric structure. For the surgery scheduling problem, all groups started with variations of randomised GREEDY, though sometimes only as a baseline for comparison. Frequently, they extended their approaches with local search (GRASP), in multiple cases using improvement graphs to deal with large search neighbourhoods. Groups also implemented simulated annealing and integer programming based approaches.

In terms of evaluating their algorithms, as showcased in their report and final presentations, students used a range of mathematical tools from the lecture. By determining lower bounds for the best solution quality, they managed to estimate their solution quality. Furthermore, students analysed the run-time and memory requirements of their algorithms.

4 SUMMARY AND OUTLOOK

Based on student feedback, the active learning within the course and the project case were well received. Furthermore, the project reports and presentations showcased that students were able to implement techniques from the lecture and to modify them to suit their needs when dealing with a real-world problem. That indicates that the teaching approach successfully contributed to students achieving the learning outcomes, which is in line with established literature on active learning (Felder and Brent 2016).

It is notable that students remarked as an exceptionally positive fact that MaHeu only requires prerequisites that students had learned before. This would appear obvious, but it apparently is not – an issue for discussion within our faculty.

Furthermore, we find that operational research not only allows for, but indeed is well-suited to PBL and case-based learning. We believe that the OR and DO community would profit from sharing more respective teaching contents. In our case, both cases were based on our own group’s research and both cases can easily be extended to provide follow up work for students interested in a thesis, e.g. by including uncertainty, rostering or bed management in the case of surgery scheduling. This offers opportunities for both sides in terms of recruiting motivated students to be part of ongoing research work.

In the context of RWTH, it would also be interesting to compare teaching approaches. There is another lecture offered on heuristics optimization with comparable LOs for students from business administration and business engineering, but a very different teaching concept based on an inverted classroom paradigm with assessment through a written exam.

A possible extension for our course would be to offer different cases to each group or even set the groups based on case preference. While this does complicate grading and preparation, it also offers students more choices in determining their learning process.

Finally, we would like to point out that the absence of research on higher education OR and DO stands in stark contrast to the evidence-based and optimisation focus mindset of the communities. Closing this gap remains a challenge for both instructors and researcher in the field of OR and DO. Specifically, drawing from established research in engineering education may enable more successful teaching and learning not just generally, but also specifically in the field of OR and DO.

ABSTRACT

Engineers frequently encounter sociotechnical issues in their work, so it is critical that they are prepared to address complex, real-world issues that require both technical and social expertise. Engineering accreditation criteria further underscore the importance of understanding sociotechnical issues by expecting engineering undergraduate programs to address ethical, global, cultural, social, environmental, and economic considerations in student outcomes. However, most engineering instructors were educated with a deep technical focus, have little experience outside of engineering, and feel ill-equipped to integrate non-technical topics. As a result, engineering is often taught in the undergraduate curricula from a purely technical perspective, with an emphasis on calculations and mathematical modelling, and without mention of social issues.

In this paper, we outline a new project to help engineering instructors integrate sociotechnical issues into their classrooms. Applying proven principles of backward course design and working with a team of electrical engineering graduate students, we aim to develop and test several sociotechnical modules for the Introduction to Circuits course. Each module will be linked to technical topics addressed in the course, and each will emphasize a different social issue. We will prepare detailed

[1] *Corresponding Author*

cfinelli@umich.edu

teaching guides so instructors can easily use the modules in their own contexts, and we will assess the effectiveness of the modules.

1 INTRODUCTION

Engineering is often taught in undergraduate curricula with an emphasis on calculations and mathematical modelling and without mention of social issues. But real problems are broader – they are multidimensional and interdisciplinary, and they encompass complex sociotechnical issues [1]–[4]. To prepare graduates for the workforce, instructors must equip students with both technical and social expertise.

Engineering accreditation criteria (e.g., ABET [5] and the European Network for Accreditation of Engineering Education [6]) further underscore the importance of understanding sociotechnical issues by expecting engineering undergraduate programs to address ethical, global, cultural, social, environmental, and economic considerations in student outcomes. Despite these criteria, however, typical engineering undergraduate curricula focus on the technical domain and often exclude social issues [7]–[11]. This focus reinforces normative cultural beliefs about engineering by inherently valuing technical issues and devaluing social ones, supporting the status quo of engineering as “objective”, and obscuring that engineering is done by, for, and with people [12]–[14].

Introducing sociotechnical issues into the engineering classroom can be difficult. Most engineering instructors have been educated with a deep technical focus, and though they may see the value of integrating sociotechnical issues into their courses, they often have little experience outside of engineering and feel ill equipped to integrate non-technical topics. Through this project, we aim to make it easier for engineering instructors to integrate sociotechnical issues into their classrooms.

Specifically, we will apply proven principles of backward course design and work with a team of electrical engineering graduate students to develop and test several sociotechnical modules for the Introduction to Circuits course. Each module will leverage fundamental circuits’ topics and will emphasize a different sociotechnical issue such as conflict minerals used for electronics or issues related to electric vehicle (EV) battery life cycles. We will prepare detailed teaching guides so instructors can use the modules easily in their own contexts, and we will assess the effectiveness of the modules in reinforcing both technical and social content of the module and in promoting students’ sense of social responsibility.

2 THE MODULES

Our sociotechnical modules will each integrate a specific social issue with relevant circuits’ content to help students see engineering as a sociotechnical endeavour. To maximize the learning potential of the modules, we will employ the principles of backward course design – including Understanding by Design [15] and principles of constructive alignment [16]. Accordingly each module will include learning objectives that address both social and technical considerations, post-class assessments (problems for homework and exams), and instructional activities that are all aligned with each other (*Figure 1*).

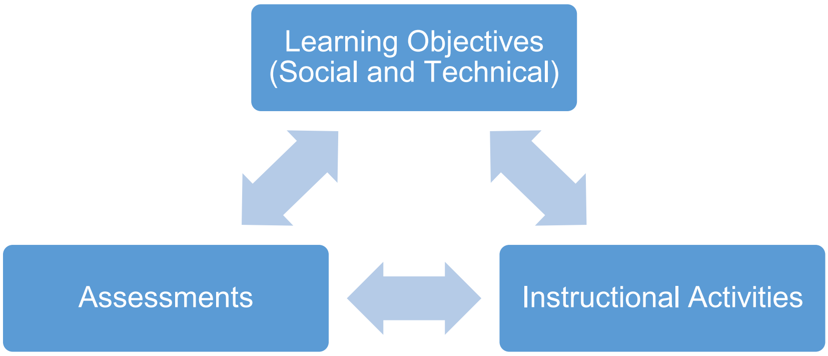

Figure 1. Backward course design

To make it as easy as possible for instructors to integrate the module into their courses, we will develop detailed teaching guides for each. The teaching guides will include sample slide decks, detailed lesson plans, and lecture notes. We will also provide assessment materials (e.g., sample homework problems and exam questions) as well as other resources to scaffold faculty in their use of the module.

2.1 Module 1: Conflict Minerals

As our first module, we will leverage an existing sociotechnical module that focuses on conflict minerals [17] and connects with basic circuits' principles of capacitors. It introduces students to social issues involved with mining of "conflict minerals" (e.g., tantalum, a material frequently used in fabricating the capacitors found in smart phones and other familiar consumer-electronic devices) in the Democratic Republic of the Congo. We outline learning objectives (which include both social and technical considerations), assessments, and instructional activities for this module in Table 1.

Students do some technical calculations related to capacitors, they discuss strategies and challenges faced by circuit designers in light of the social issues related to conflict minerals, and they research and present about different conflict minerals policies of several popular electronics companies. Finally, students make a critical comparison of the conflict mineral policies for various companies and reflect on their role as engineers. Homework for the module is integrated into regular class assignments, and technical calculations as well as oral presentations and discussion are included in the module.

Table 1. Learning objectives, assessments, and instructional activities for Module 1

Learning objectives	Assessments	Instructional activities
• Analyze capacitors as electrical devices • Define conflict minerals and describe at least two social issues surrounding them • Describe where conflict minerals are used • Describe potential options for engineers concerned with the social implications of conflict minerals	• Complete calculations and internet research about conflict minerals • Prepare presentation about conflict minerals policies and social implicatons	• Learn about and discuss conflict minerals and the social implications • Present research about conflict minerals policies

2.2 Module 2: EV batteries

Our second module focuses on issues related to life cycles of EV batteries [18], and it connects with basic circuits' principles of the voltage divider. It introduces students to issues involved with the growing number of end-of-life EV batteries and concerns related to recycling them by applying principles of the circular economy. We outline learning objectives (which include both social and technical considerations), assessments, and instructional activities for Module 2 in Table 2.

Table 2. Learning objectives, assessments, and instructional activities for Module 2

Learning objectives	Assessments	Instructional activities
• Design a voltage divider for a DC voltage source to illustrate repurposing EV battery packs • Estimate the energy available in end-of-life EV batteries • Describe social risks introduced by recycling EV batteries that could be alleviated by applying circular economy principles.	• List various social risks introduced by recycling EV batteries • Write about the principles of the circular economy and how it can be applied to repurposing EV batteries • Use a loaded voltage divider model to calculate voltage, resistance, and power of a second life EV battery pack • Estimate the effect of energy degradation on EV battery repurposing.	• Listen to a podcast about the circular economy and answer some related questions • Estimate and discuss the future voltage capacity of existing EV batteries and the potential demand that could be met using them • Learn about the circular economy and how it relates to circuits concepts and EV batteries • Discuss ways to use the circular economy to repurpose batteries.

2.3 Additional modules

To develop additional modules, we will recruit a cohort of electrical engineering graduate students from across the U.S. We will design a workshop to introduce the cohort to both proven course design principles and the importance of integrating sociotechnical topics into traditional engineering courses. The cohort will then collaborate to propose a series of sociotechnical modules for the Introduction to Circuits course, and they will ultimately prepare detailed teaching guides for each.

We expect that establishing a cohort will introduce diverse perspectives into the module design and will create a sense of community among the graduate students as they tackle the challenging tasks related to developing the modules. Students in this cohort will be able to help recruit instructors to implement the modules at diverse institutions, and they will themselves be prepared to implement the modules in their own courses and to include sociotechnical content in their teaching when they become professors. Using a cohort approach in this way will hopefully increase the likelihood of changing the culture of electrical engineering teaching broadly.

3 ASSESSING THE IMPACT OF THE MODULES

As we introduce our modules, we will evaluate the extent to which they achieve both the social and technical learning objectives. Because we will have applied proven course design principles, we will do this by studying student responses on the assessments. Specifically, we will review student solutions to the relevant homework assignments and exam questions and will summarize student responses to open ended reflection prompts, thereby generating evidence about how well they achieve our learning objectives.

We will also assess the impact of the modules on students' social responsibility attitudes (i.e., their sense of social responsibility and their adherence to normative engineering cultural beliefs). To do so, we will conduct student interviews and focus groups, and we will develop and administer a student survey instrument as a pre- and post-course assessment measure. The survey will include a combination of pre-tested and previously validated survey items as well as demographics items (e.g., sex, race/ethnicity, class level, and field of study). Key components of our survey, include a subset of items from the Engineering Professional Responsibility Assessment instrument (EPRA, [19]) to assess students' social responsibility attitudes and items from a published survey about engineers' training in professional responsibilities [20] to assess students' adherence to normative cultural beliefs.

4 NEXT STEPS

We plan to test and deploy each of the modules using a four-stage process:

1. Pre-pilot the module in a small circuits course at a small, private institution taught by a member of the research team
2. Pilot the module in a large circuits course at a large, public university taught by another member of the research team
3. Launch the module in large circuits courses at the same large, public university taught by an instructor not part of the team
4. Deploy the module in at least four other courses at diverse institution types (including minority-serving institutions and specialty schools)

We will refine the modules at each stage using student and instructor feedback.

Our project is a work in progress. To date, we have developed and pre-piloted Modules 1 and 2. After developing our student survey, we will pilot those two modules and then launch them broadly. We have just begun to formulate our plans for the electrical engineering graduate student workshop, and we will start recruiting students soon. We expect to be able to broadly disseminate our project findings and share detailed teaching guides with instructors across the globe within a few years.

5 ACKNOWLEDGMENTS

ABSTRACT

Universidad Francisco de Vitoria (UFV) in Madrid (Spain) and Universidad Vasco de Quiroga (UVAQ) in Morelia (Mexico) seek the comprehensive academic training of students: not the mere development of technical skills, but also the personal and soft skills that enable them to face their professional reality.

Educational missions in both institutions aim for sustainable development oriented towards people and the societies in which they are immersed. Their substantial actions have been designed, in such a way that active methodologies and innovative proposals are included. Among them, it is worth highlighting the provision of a personalized support system for students, in which, through a competence itinerary with their tutors, issues are addressed to help them to full development.

An added value has been identified by applying this mentoring system at engineering programs (mainly based on hard skills), when supporting students in the development of other skills.

A comparative study was carried out on the differences and similarities of the programs of both universities, from the point of view of the people who mentor and guide students. Thanks to those contributions, we have information that will allow us to adapt the processes and thus respond more adequately to the needs of engineering students in their first undergraduate degree courses. The focus group technique and a survey were used in the process.

1 INTRODUCTION

1.1 Background

The word accompany comes from Latin *cum-pane*, i.e., to share the same bread, literally “with bread”. It means that we are together in the process, putting both lives at stake, with their different degrees of experience, to reach mutual learning (Nicholson 2021, 281-290).

Accompanying is a human response that comes from the heart, and it is focus on the other needs. It means to walk together (who accompany and the accompanied person), and allow the other be, letting him awaken his own being. To accompany is to be, to welcome, to listen, to share, and to go out to meet the other. Accompanying is an art because the success of the accompaniment is not that of the one who accompanies, but that the other acknowledges feeling accompanied. Time is required to accompany, silence is required from one to listen to the other, and it is necessary to change the rhythm and adapt to the other. The one who accompanies does not advise, does not have magic recipes, but seeks to illuminate from his own experience those of the accompanied. Accompanying is fundamentally the action of “walking next to” a person, sharing some part of his/her itinerant life. Accompanying is, in various ways, sharing the journey and their experiences (Kaufman et al. 2022, 33-45).

1.2 Mentoring at UFV

Mentoring activities developed at the UFV in the first year of Industrial Engineering students are framed in the Knowledge Management and Human Skills (KMHS) course, offered annually with recognition of 9 credits in the student's curriculum (Queiruga-Dios, et al., 2023, 907).

Mentoring process includes student's individual accompaniment, through a mentor, who is a professional trainer equipped with the necessary competences to perform this task. During classes students are accompanied by their teacher and their classmates, they are part of a community. The KMHS course aims to contribute to the comprehensive training of the student, it is a compulsory transversal and propaedeutic subject that proposes the acquisition of competences and skills through a comprehensive experience. This course is developed as an experience made of different actions. The acquisition of competences becomes a means of personal fulfillment by asking the student a question -"what do these professional skills have to do with me, with my vocation and with who I am?; and how can I live those competences with sense?"-, and then, invite him or her to discover a possible answer: that their future career depends to a great extent on how that student build him or herself today (Allen et al. 2004, 127; Crespí 2022, 852-873).

The process of accompanying students is developed through 6 meetings with each student. During these sessions, a specific route of discovery is presented to students, through questions, exercises and actions that allow them to make decisions throughout their first year at university. These meetings seek that the student acquires competences as specific as proactivity, time management, deep insight, etc. This process is carried out through questions that challenge the student to generate creative habits, and using the CRECER methodology, i.e., with Concrete, Realistic, Empathic, Programmed, Focused, and Challenging actions (CRECER is the Spanish acronym that specifically means *grow* in Spanish) (Díaz-López, 2022).

1.3 Tutoring at UVAQ

The objective of the personalized accompaniment program at UVAQ is to go along with students in their integral development, focusing on 5 of the dimensions of the person: physical, psychological, academic, social, and spiritual, through the support of tutorials, growth workshops and personalized psychological care.

The establishment of an aid and accompaniment relationship arises from students and tutors contact during classes and from scheduled individual interviews. Students have the possibility of accessing two tutoring sessions throughout the semester, during which they have a space and time to share their experiences, ways of thinking and feeling, in the same way that they explore and discern about their lives, supported and guided by the tutor. These interviews take place at the university campus.

The tutor is the person who accompanies the student throughout the training in the personal, spiritual, psychic-emotional field. The tutor has a moral and spiritual sense, trained to develop this specific function. He or she has a competent academic level based on humanist and learning theories to help young persons on their way during their time at the university. Tutors task is to serve, because they have the knowledge, experience, training and maturity to assist and attend students (Burgess, van Diggele, and Mellis 2018, 197-202).

Currently, the work team for the tutoring of the personalized accompaniment program is made up of thirteen tutors and three external specialists in Psychology. The specialists and the tutors attend to training sessions organized by the educational guidance department. This training is given twice a year in an inter-semester period to deal with the necessary issues for the development of their activity.

The student's commitments with the personalized accompaniment program are the following: To know themselves, to develop and discover their abilities as a person; to have a commitment to the tutor in the development of the activities agreed upon by mutual agreement and become aware that the only person responsible for their training and growth process is oneself; and to participate in the tutor evaluation processes, in accordance with the mechanisms established by the university.

2 METHODOLOGY

A mixed methodology has been chosen for this study. First, an ad hoc questionnaire called “UFV mentoring-UVAQ tutoring for engineering students” has been conducted, based on qualitative questions. Second, a focus group has been held with the agents involved in the study. Both instruments have provided a global vision of the two accompaniment systems and have made it possible to compare them. The focus group stands out especially, because it made possible to know each other and develop this cooperative and collaborative study.

The focus group has its origin in the qualitative method of the interview, but tries to cover more agents, so that different opinions can be collected at the same time, in addition to generating a highly enriching dialogue between the parties. It is a method that lies between a meeting and a conversation, defined by some authors as a debate among a group of people, on a specific topic and with an experienced moderator (Hauer et al. 2005, 732-734; Sim and Waterfield 2019, 3003-3022).

The chosen sample was made up of advisors and mentors who accompany engineering students from the UFV and UVAQ universities. Students who have participated in the accompaniment process could have been chosen to tell their experience of the accompaniment system of these universities, but on this occasion, it has been preferred to carry out a self-analysis by those who do the accompaniment work in order to better understand both support systems and enrich themselves with the benefits of each of them. This methodology has been chosen because it provides great qualitative information (Gundumogula 2020, 299-302).

Qualitative analysis through focus groups serves as a channel for dialogue between the agents involved through which opinions, concerns, good practices and experiences are shared. In case of the UFV, the sampling of this study is of a non-probabilistic type by judgment or deliberate. Of the 270 mentors, only those who carry out their work in the polytechnic school, in the Systems Engineering degree were chosen. At the UVAQ, only those who currently carry out their work in the Faculty of Engineering were chosen.

3 RESULTS

A group of eight teachers participated in this study, 75% corresponded to women and the remaining 25% to men, 25% being mentors from the UFV and 75% tutors from the UVAQ. Specifically, the faculties in which participants developed their work as mentors were Systems Engineering and Computer Security, Computer Engineering and Systems Engineering.

On average, mentors have developed their activity for 6.2 years. However, the dispersion of the values is significant (with a standard deviation of 6.15), since some of the teachers have less than 1 year of experience as mentors, while others have 15 years of experience. Fig. 1 shows this distribution, grouped by the experience of the teachers/mentors who participated in the study.

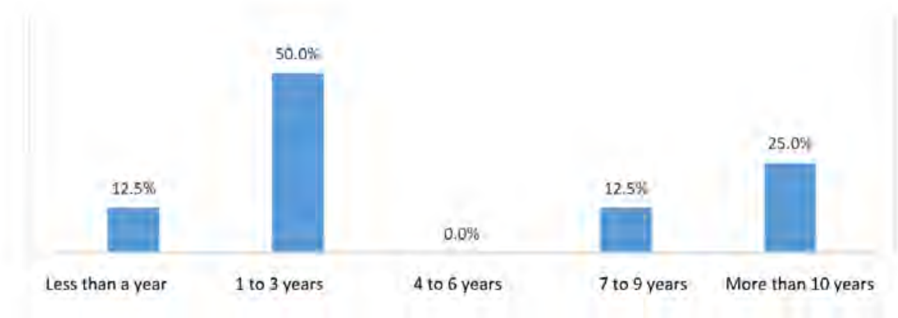

Fig. 1. Experience of the teachers/mentors

Regarding the experience of the mentors in engineering accompaniment, it was found that the majority have worked as tutors between 1 and 3 years. It is important to highlight that 37.5% of the consulted mentors have more than 3 years of experience and only 12.5% have less than one year of experience in processes of accompanying engineers.

3.1 UFV mentoring-UVAQ tutoring for engineering students

The instrument "UFV mentoring-UVAQ tutoring for engineering students" was applied to the teachers who carry out this work, having a total of eight answers related to the tutoring tasks and the advice that this implies. The following questions were proposed:

1. What has been the most difficult experience you have had as a mentor/tutor?
2. What has been the most satisfying experience you have had as a mentor/tutor?
3. Write a word that explains what to be a mentor/tutor means.
4. What do you think are the strong points of the student accompaniment system in your institution?
5. What do you think are the areas for improvement in the student accompaniment system in your institution?

Regarding the experiences classified as difficult that were obtained by the mentors/tutors, an open option was chosen, which allows a better approach to the qualitative logic of their own experiences. These open responses were categorized, and some of them appears repeatedly throughout the results: problems related to students suffering, the difficulty in helping young people to process their emotions and anxiety management, and the presence of violence in students' life, even a kidnapping case significantly affected one of the students.

In general, personal aspects related to the mentor or tutor tasks were not mentioned, the answers were oriented to the intrinsic difficulties of working with people who are going through complicated situations in their lives. The terms that were mentioned most frequently were: loss, suffer, pandemic, mourning, anxiety and violence.

Tutors and mentors were asked about those gratifying experiences related to their work as tutors/mentors during student's accompaniment. Once again, the open responses were categorized and a diagram was generated (see Fig. 2), which shows the network of most frequently mentioned concepts and the interaction between them, being the keywords: accompaniment, students and improvement, and the rest of words are the pleasures that give meaning to the keywords.

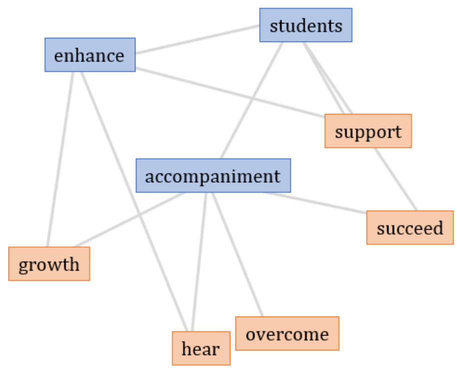

Fig. 2. Chart with key descriptors of the most satisfying experiences you have had as a mentor/tutor

When questioning the mentors about the strong points of the program, they identified its comprehensiveness, the constant training of the tutors, the promotion of spaces for reflection and self-knowledge in the students through active, empathetic and an active listening, free of prejudices, as well as a space that provides containment and that allows guiding students with psychological or psychiatric care (when needed) (Fig. 3).

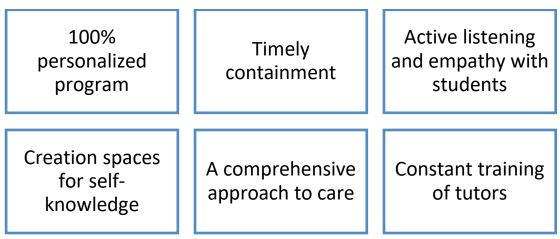

Fig. 3. Strengths in the student accompaniment system at its institution

Finally, tutors were asked about the improvement possibilities that they identify in the student accompaniment system (in their own institution), and they pointed out the need for the tutors to have an adequate number of students that allows them to maintain a personalized treatment, to have better spaces for tutoring and mentoring sessions and increase the time dedicated to them.

This opinion poll allows us to get some results from people who face the day-to-day work of tutoring students in the institutional support systems from the Francisco de Vitoria University and the Vasco de Quiroga University and becomes a very important input to improve the service offered, while providing better support to mentors and students in a process that seeks to be comprehensive, empathic and humane.

3.2 Focus Group

With the group of eight teachers, a focus group was raised to discuss about the following issues:

1. In general, what would you say about the characteristics of first-year undergraduate students?
2. Specifically, what are the characteristics of engineering students? (brief description using adjectives).
3. Do you think engineering students have specific needs compared to other students in other degrees? (Only aspects that appear different or significant compared to other students).
4. Do you think that students positively value the accompaniment provided by their university? Why?
5. In what aspects do you think we can help engineering students?

In the case of the first question, mentors and tutors consider that students who are more confident in terms of the degree they have chosen, feel excited and eager to start this new stage of their lives and therefore they show a high level of motivation.

In recent years mentors and tutors show an increase in social immaturity on several students and great affective needs that they can verbalize naturally. This could be a consequence of the pandemic.

Regarding the second question, the mentors and tutors of engineering students rate them with the following adjectives: students who are especially organized, competitive, responsible, and with high levels of self-demand. Again, they speak of having a certain immaturity and irresponsibility in some cases, especially when they do not find the necessary motivation, with little contact with emotion or only superficially. A generalized apathy towards issues that have nothing to do with their discipline is perceived. In the case of engineering majors, there is a male majority, and it seems that this makes it difficult for them to express their emotions (in this sense, tutors and mentors point out that it may be something cultural). They also describe them as reserved, with logical and mathematical thinking, skilled in process issues, and with certain difficulties in relating.

Answers to the third question revolve around the emotional issue, reiterating that they are less expressive, have a hard time expressing their emotions and are more reserved than students in other grades.

Regarding the fourth question, all the mentors and tutors understand that yes, the assessment of engineering students is positive, but that in most cases it is difficult for them to understand what the support offered by both institutions means and they tend to start the processes. quite closed, but when they understand it better their attitude changes radically, they are open to the process and appreciate it.

Finally, to the fifth question, the answers refer to maintaining an attitude of listening and permanent availability with them, creating with them a safe environment in which they can tell about the situations they are going through without being judged. Added to this is the need to provide them with information on what the accompaniment programs consist of. Another answer raises the possibility that one way to help students is precisely not to label them for what they are or how they are, to give them the space to be themselves.

4 SUMMARY

Accompaniment is a fundamental tool in the teaching-learning process. It provides students with a safe environment in which they can be themselves, be able to express their concerns and difficulties, and seek, with the help of others with more experience, the path to reach their goals.

Mentors and tutors report that the most difficult situations they have addressed in their work are the emotional wounds and suffering that students show in difficult situations. At the same time, the most rewarding experiences are related to how students deal with these situations and how they can generate an interpersonal relationship with the mentor or tutor. Despite the difficulties faced by first-year engineering students, such as poor socialization or difficulty to express their emotions, thanks to the accompaniment they can significantly improve these aspects according to the perception of mentors and tutors.

Both mentors and tutors highly value their work, expressing great personal satisfaction for working with students. It is important to them to see how students mature personally in the first year of their degree. As one of the trainers shared in the focus group: “it is a gift to be able to look into the lives of the students, who simply share with us who they are; it is a gift and a responsibility, because we are treading on sacred ground”.

To continue developing their work, mentors and tutors consider that it is necessary to adapt the times and spaces with the students, to share more sessions with them, going deeper into the topics already proposed in the process, as well as to adapt the number of students per mentor/tutor so that they can develop their tasks with quality.

ABSTRACT

Last year we presented the first phase of our on-going research project - a collaboration between researchers at UCL and Academic Development team members at Ansys Ltd on sustainable digital transition in education. The results of the first phase were published in proceedings of the 25th International Conference on Interactive Collaborative Learning (ICL2022). We developed a framework to explore how technology companies, with a focus on education, approach sustainability in education through their products and their practices and what makes them impactful, focusing on a specific case of Ansys Granta EduPack.

The framework was the amalgamation of two previous analyses that explored i) how learning outcomes associated with the UN Sustainable Development Goals could be used to foster ways in which learning for sustainability can be implemented in Higher Education, and ii) how the same learning outcomes translate to concepts of capital used by companies to assess sustainability impact.

[1] Corresponding Author: G. Giannopoulos
g.giannopoulos@ucl.ac.uk

In this part of the study, we present the second phase of our project, the development of two questionnaires for university students and educators based on the framework, described earlier. The questionnaires focus on assessing sustainability awareness and involvement of staff and students of Science and Engineering Departments in sustainability activities, using a Whole Institution Approach.

In this paper we present preliminary data from the piloting of the questionnaires during a materials education workshop for University Educators organised by Ansys Ltd in Cambridge UK. In the third phase of this research project the questionnaires will be shared more widely with staff and students in science and engineering focused faculties internationally.

1 INTRODUCTION

1.1 Sustainability as an Institutional dimension for Universities

Sustainability is a crucial institutional dimension for many Universities as students have been shown to select University departments to study based on their engagement with sustainability and recent surveys they have calculated that 88% of all undergraduate students in the UK would like their courses to be directly related to sustainability and the UN SDGs (Students Organising for Sustainability 2022). Impact and value creation at the job environment is also a factor influencing how recent graduates choose a work place and to quote the above mentioned survey:

"… the majority of students still say the chance to work in an organisation that makes a difference to environmental and/or social issues is something they would consider at the application stage but 77% would accept an annual salary sacrifice of £1000 to work for an organisation that has a good environmental and social record, down from 80% in 2020-21." (ibid)

Sustainability is an interdisciplinary topic and many Universities are recognising the need to equip their students with skills for sustainability as they will enter a complex world of unprecedented change in which they will have to make crucial decisions (Lozano-García, Huisingh, and Delgado-Fabián 2009). Universities are embedding sustainability as either a module within specific disciplines, an elective course that students can take as part of their University studies, an interdisciplinary programme of study at postgraduate level usually and less so at undergraduate level or they are trying to reform their curricula so they embed it as content and pedagogy which is the most complex of all (Kioupi and Voulvoulis 2022).

However, for a University to be truly sustainable, it usually has to embed sustainability using what is called the Whole Institution Approach (WIA) as advocated by UNESCO (Wals 2014). This approach talks about engagement with sustainability through all the dimensions of the institution that is through research, teaching and learning, governance and operation as well as community engagement. This is thought to be a systemic approach to integrate sustainability in an institution as it enables a change of culture in the University and requires committed and inspiring leadership, usually of a transformative nature (Tilbury 2011). It starts with integrating sustainability to the vision and mission of the University so it guides its strategy in how the university operates, does research, provides education and relates to internal and external stakeholders. Some steps on how this can be achieved in terms of using the SDGs as a guiding framework have been discussed in the literature and can be useful in helping University stakeholders start a discussion on what this would look like in their University (Kioupi and Voulvoulis 2019).

Apart from greening the campus initiatives which are important for offering a lived experience of sustainability for students and staff and offering engagement opportunities beyond specific roles, Universities have a social role to fulfil which is linked to the research they conduct. This in the times of existential crises we are currently being faced with could be related with providing solutions to challenges related to the SDGs or even ways forward e.g. solutions to climate change, safe water access, sustainable urban environments or even combating inequality and poverty (Lukman and Glavič 2007; Australia/Pacific SDSN 2017). Through the education they

[1] *Corresponding Author: G. Giannopoulos*
g.giannopoulos@ucl.ac.uk

offer they can empower their students with sustainability competences, which are complex constellations of knowledge, skills, values, attitudes and behaviours that have to do with tackling problems holistically but also with imagining and enabling alternative sustainable futures (Kioupi & Voulvoulis, 2022). With regards to community engagement, Universities are starting to develop hubs, such as living labs, community spaces in which different departments contribute as testbeds for sustainability but also relationships with local communities, organisations and businesses to offer solutions or to co-produce knowledge with citizens and other professionals and come up with innovative ideas e.g. maker spaces (Leal Filho et al. 2019).

One important area of sustainability integration within a University's teaching practice is through the digital transition and technology companies can be useful in linking their educational offering to clear educational outcomes that will benefit the University's transition as well as help students and staff develop digital skills. This paper links our previously published framework for assessing sustainability integration in educational products of technology companies with the views of educators and students on educational outcomes for sustainability through the design and testing of quantitative measures that aim to research views of how Universities are incorporating the WIA in their realities as well as how educational software for sustainability is perceived and utilised.

1.2 Background and rationale

Sustainable digital transition (SDT) is the name we are using to describe the integration of sustainability in the digital economy and it is linked with "greening the economy" efforts as well as with creating enabling policy to allow for innovation related with environmental, economic and social targets (European DIGITAL SME Alliance n.d.). Education is an important part of the economy as it is related with skills essential for the workforce, as well as with innovation and tackling of pressing challenges. So there is also an effort towards the sustainable digital transition of education by the integration of the UN Sustainable Development Goals in education (Kioupi and Voulvoulis 2019, 2020; Sachs et al. 2019).

In the first phase of our case study, we observed that the SDGs were attached to learning objectives that could be used to influence the cognitive, socio-emotional, and behavioural learning of students (UNESCO 2017). Thereby, the SDGs can contribute to sustainability awareness raising among students. However, in their original form the SDGs were too complex to implement in education. We also observed that the products and practices of EdTech providers had an influence on student learning, although it was not initially clear how the products and services related to learning objectives. We developed a framework to explore relationship between the SDGs, learning objectives, EdTech products and practices. To aid our comprehension we focused on the use of Ansys education-focused software. Details of the framework can be read in a previous publication (Vakhitova et al. 2023).

The findings of the framework indicated that EdTech providers use their CSR (and CR) reports to demonstrate their approaches towards sustainability. In these reports sustainability was viewed as different forms of capital (Maack and Davidsdottir 2015), two of which (human and social) aligned well with the learning objectives of courses that link to sustainability and were aligned in the used Ansys products. We then

[1] *Corresponding Author: G. Giannopoulos*
g.giannopoulos@ucl.ac.uk

identified which of the SDGs were attached to the learning objectives associated with human and social capital using a previously published framework for integrating the SDGs into educational programmes that takes a systemic approach instead of accounting for separate SDGs (Kioupi 2021).

We highlighted that the framework offers a consistent way by which sustainability integration in digital tools/educational software can be assessed using environmental, social and economic capitals (M. Ashby 2015) as well as enabling conditions for the UN SDGs (Kioupi and Voulvoulis 2020) as demonstrated in the case study of Ansys Granta EduPack (Vakhitova et al. 2023; “Ansys Granta EduPack | Software for Materials Education” n.d.). This fills a gap in the existing literature and practice and allows both educational institutions, such as Universities, and EdTech companies a coherent way of providing evidence of the links to sustainability of their programmes and services but also provides a way to link with learning outcomes and quantify the impact on student learning and sustainability competence development.

Usually sustainability integration in education, is representative of a top-down approach, originating from bodies, organisations and businesses outside of the educational institutions in which the changes are to occur, which provide the guidelines to educational institutions to do so. Furthermore, the alignment between the SDGs, learning objectives, EdTech products and practices, is characteristic of an incidental approach towards sustainability whereby raising awareness among students is an additional benefit rather than an intended outcome (Brinkhurst et al. 2011). The incidental nature of the relationship between the SDGs, learning objectives and EdTech implies that further exploration is needed through the validation of our framework.

Previous literature advocates the use of questionnaires to measure attitudes and behaviours regarding sustainability. Gericke et al. (Gericke et al. 2019) presented their investigation of Sustainability Consciousness - “an individual’s experience and awareness of sustainable development”. To gather individual views the researchers used a questionnaire, which explored three key aspects of consciousness, these being Knowingness “the state of mind in which a person thinks something to be the case” Attitudes & Behavior. All three aspects are similar to our focus on exploring the cognitive, socio-emotional, and behavioral learning of students (UNESCO 2017) which implies that a similar construct would be appropriate for the second phase of our case study.

At present, the first phase of our case study has explored how EdTech providers approach sustainability in education through their products and practices. However, to fully explore what makes EdTech products and practices impactful regarding sustainability, we need to obtain the views of faculty staff and students. These views are representative of bottom-up perspectives (of students) and often overlooked middle-out perspectives (of faculty staff). We will look for alignment between the top-down, middle-out and bottom-up perspectives. In the second phase of our case study, we will deploy a whole-institution approach (WIA) to explore the extent of sustainability awareness and integration among faculty and students, following the below definition of a WIA:

[1] *Corresponding Author: G. Giannopoulos*
g.giannopoulos@ucl.ac.uk

A "whole institution approach" means that all aspects of an institution's internal operations and external relationships are reviewed and revised in light of SD/ESD principles… A whole institution approach means that the strategy of the institution, and ultimately its culture, is oriented towards sustainable development." (UNECE 2008)

The extent of alignment between the perspectives would be an indication of what makes educational technology products and practices impactful in education. Strong alignment may be indicative of co-ordination and collaboration between faculty, students, and EdTech providers. Weak alignment may suggest that SDT in education is incidental and lacks co-ordination. In both scenarios it may be possible to identify strengths and weaknesses of SDT enabling more coherent strategies to be created and deployed.

2 METHODOLOGY

2.1 Design and development of surveys to gauge student and staff experience of sustainability in Universities in the UK

We are focusing our research on how Universities practice sustainability and we wanted to understand how they embed sustainability through WIA. We are focusing initially in the UK and in departments related with science and engineering but we want to expand to departments with orientation to social studies as well as to those outside the UK. This will allow us to collect data from diverse Universities and map what they are doing but also how students and staff are experiencing these efforts. To start our research and establish a baseline of how sustainability is practised we developed two questionnaires to understand how University educators and students engage with sustainability on and off campus. The questionnaires were built using previously published and validated questionnaires as well as we included some new questions that would allow us to cover as many aspects of the WIA as possible as well as to collect data on how Universities are using educational software related to sustainability (Barth 2011; Gora et al. 2019). The use of technological educational solutions (software) is a promising way to engage students with sustainability and the development of students' digital skills is crucial from an employability point of view.

The questionnaires include four areas of engagement with sustainability: curricular, institutional, research-based and community-based. The questionnaire for University staff also includes a question about the use of educational software. The questionnaires include mostly close-ended questions answered on a Likert scale on a Not at all to A great extend range, including a Don't know answer, yes/no/don't know options or a sliding scale and some open-ended questions to gain more descriptive and qualitative information about the aspects of sustainability they feel are already integrated or they would like to see integrated in the future.

The student questionnaire includes 12 questions and starts by asking if the students are undergraduate or postgraduate what is their University and department at its introductory part. It also asks about courses offered in relation to sustainability as well as any curricular integration of it and seeks to also check for any gaps the students can identify in their curricula. The next section is about the sustainable use of resources and the enhancement of biodiversity as well as the provision of opportunities for the community on and off campus to engage in new connections and solutions building for sustainability. The final part is concerned with the opportunities

[1] *Corresponding Author: G. Giannopoulos*
g.giannopoulos@ucl.ac.uk

that are specific to students in relation to their engagement with sustainability on and off campus.

The staff survey starts in a similar way and includes 16 questions, it asks about staff professional role in the university, University name and department. Then it goes on to questions about curricular integration of sustainability and identification of gaps as well as sustainable use of resources and community engagement with sustainability. Then it includes a section about opportunities for research related to sustainability for staff and students, professional development offered to staff in relation to sustainability integration and criteria for employment related to sustainability. The final section concerns collaboration with technology companies and the use of educational software in the area of sustainability that they are already engaging with or they would like to in the future and the areas that they would like to address.

To increase the questionnaire reliability and validity we asked colleagues from the Department of Physics and Astronomy at UCL to review them and provide comments to us. We also asked a group of 8 Year 3 students from the same department, who were engaging in an open project that links Physics and engineering with sustainability, to check for areas of difficulty and provide feedback. They were shared with colleagues and students at ETH Zurich for their consideration and feedback as a target population outside the UK so the relevance of the questions to audiences outside the UK could be increased. The questionnaires were improved based on the comments, received and finalised for submission for ethics approval by UCL (this process has not been finalised yet). The next step is the dissemination of the questionnaires in UCL, other UK Universities and then abroad, followed by the data collection and analysis. A part of the staff questionnaire was used for collecting responses from participants at the “Teaching Sustainable Development using Ashby’s 5-step method” workshop that took place in Cambridge UK (3/4/23), helping to gain initial insights. It is described in the next part of this paper. The process of developing and validating the surveys is presented in Figure 1.

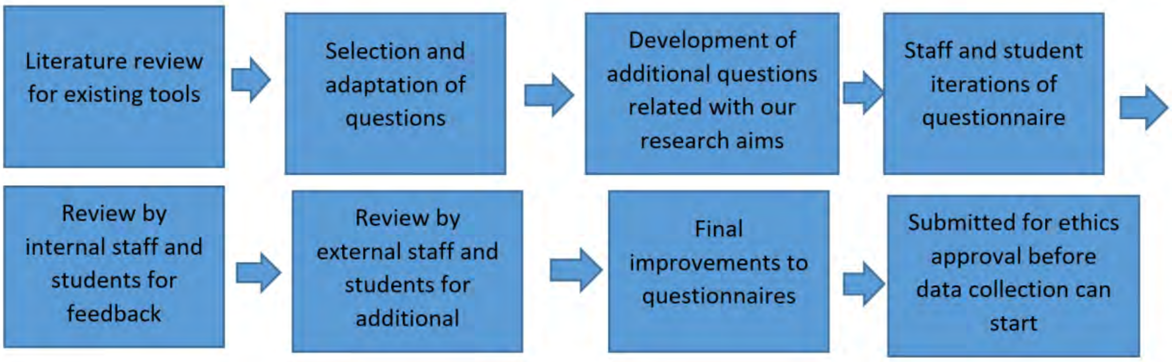

Fig. 1. Flow chart that shows the steps of questionnaire development.

2.2 Materials Education Workshop

On the 3d of April, as a part of the International Materials Education Symposium, authors from Ansys Ltd (Academic Development Team) held a workshop, dedicated to Materials and Sustainability, named “Teaching Sustainable Development using Ashby’s 5-step method” (link to the workshop). The Workshop was based on

[1] *Corresponding Author: G. Giannopoulos*
g.giannopoulos@ucl.ac.uk

developments in Mike Ashby's second edition textbook "Materials & Sustainable Development" (M. F. Ashby, 2022). The workshop material (templates and slides)("Ansys Education Resources – Teaching Materials" n.d.) was used in teaching for several years in various educational establishments, aiming, among others, to support educators from technical educational establishments, embracing the social element of sustainability assessment ("Paper: Social Life-Cycle Assessment and Social Impact Audit Tool | Ansys" n.d.). This workshop has encouraged discussion on sustainability integration in engineering curriculum among participants.

The fourteen participants of the workshop, representing 10 different countries, came from various universities around the world, including Canada, Australia, mainland Europe and from the UK. These were predominantly at a level of teaching staff in engineering/materials field or combining a role in administration of education process at a university. After the workshop participants were asked to fill in a part of the staff questionnaire (6 first questions regarding Sustainability in Curriculum at Departmental Level), we have described in the previous section. The purpose of the survey and the research project was explained, and the anonymity of their responses was guaranteed. All participants agreed to complete and provided their responses to the survey.

3 RESULTS AND DISCUSSION

3.1 Materials Education Workshop results

The overall results from piloting the survey at the materials education workshop are presented in Table 1.

Table 1. Results from the main areas of the survey, distributed at the workshop Materials & Sustainable Development (3/4/23)

	Questions / Answers	Don't know	Insufficient	Sufficient	None	More than enough	Total responses
1	Sustainability courses		10	4			14
2	Global Warming/Climate Change/Science	1	7	4	2		14
3	Clean Renewable Energy/Critical Materials	1	9	4			14
4	Globalisation & Sustainable Development Goals	1	10	1	2		14
5	Curriculum/ teaching activities*		9	2	1		12
*2 participants have not responded to question 5							

Despite being a relatively small sample, the participants are the people from our target group. These are the individuals, involved in teaching with an interest in sustainability at materials, design and wider engineering faculties around the world. We will further collect data distributing the survey across universities and compare these initial results.

[1] *Corresponding Author: G. Giannopoulos*
g.giannopoulos@ucl.ac.uk

The key conclusions suggest there is still a gap in the inclusion of sustainability in the curriculum in most of these universities, specifically there is an insufficient number of courses focusing on sustainability offered at higher education establishments. The most disregarded is the topic of Globalisation and Sustainable Development Goals, as well as Climate Change and its Science, showing that crucial international policy developments such as the Paris agreement and the UN SDGs are being left out.

Some of the discussions have focused on the need for a greater collaboration among scientists and engineers and academics from arts/humanities areas to address all the complexities, sustainability offers. Suggested ways forward linked with the methodology taught during the workshop has to do with the framework/templates provided for the 5-step methodology and had an overwhelming success. This methodology helps to tackle complexity by providing a clear step to include problem statement, identification of stakeholders' concerns, a step, focusing on factual information regarding the former, and sustainability assessment and reflection parts. At the workshop, several participants mentioned that sustainability-focused new courses are being set-up at their respective departments and the topic is addressed at the top level at universities, including setting-up responsible personnel/new responsibility areas.

Specific comments from a staff member of a mechanical engineering faculty suggested the need to have a more specific course focusing on sustainable development, apart from existing specialised e.g. “ocean engineering”, “green materials”. Among the essential courses not being taught, were suggested: “Lifecycle Analysis”, “Materials Selection”, “Critical materials”, “Project management”, “Science Communication in Engineering”, “Materials Engineering”, “Materials Science & Technology”, “Sustainability & Social Impact”, “Waste Management”, and a need for more “Arts/Humanities – related subjects”.

3.2 Discussion

The preliminary findings from piloting our survey in the workshop advocate for the need to establish the baseline of what is practiced in Universities at the curricular level, but also mandate the need to see sustainability as a WIA. As evident, Universities are trying to develop new courses to tackle sustainability but sometimes these are highly specialised and they do not help students understand the bigger picture of what sustainable development is and develop general sustainability competences. This coupled with the lack of SDGs and climate change education show that crucial areas of tackling sustainability challenges are missing from curricula. However, educators in the workshop showed that when an educational software is combined with a methodology that can help them assess sustainability can be an important way of enhancing learning outcomes for students. In other words the pedagogy and specially designed educational material that accompanies the software are of utmost importance. Still the educators shared generic views such as that sustainability is a priority of their institutions and the University is hiring personnel and developing committees or other strategies to tackle it, and here our survey can clarify the areas that University is aiming to focus on regarding sustainability and help University educators and staff clarify the benefits of a WIA into their sustainability integration.

[1] *Corresponding Author: G. Giannopoulos*
g.giannopoulos@ucl.ac.uk

In this study we have established the need for the student and staff survey in alignment with our published framework as it will provide the data needed to understand how Universities are integrating sustainability and suggest ways forward. The findings of the questionnaires will be triangulated against the results of the previous framework in a new study. The aim is to evaluate the current state of sustainability integration at science and engineering focused universities/faculties, offering ways to address any gaps and to offer recommendations for technology companies to promote sustainability through their education offerings. The alignment of perspectives among staff, students, technology companies' contribution to sustainability, and our framework will be checked after final data analysis and ultimately will suggest practical steps to address sustainability awareness, educational and WIA implementation gaps.

4 SUMMARY AND ACKNOWLEDGMENTS

This paper describes the second stage of the research project, focusing on the two questionnaires for university students and educators based on the framework, which brings together UN Sustainable Development Goals and Learning Outcomes in Higher Education (published elsewhere, e.g. Vakhitova et al. 2023).

The questionnaires focus on assessing sustainability awareness and involvement of staff and students of Science and Engineering Departments in sustainability activities, using a Whole Institution Approach. The preliminary results were collected, using a part of the questionnaire for educators, and described in this manuscript. Among the main findings is that implementation of sustainability into the curriculum to tackle global sustainability challenges needs to be further improved, and this is the main goal of the third part of our effort.

We would like to thank the participants of the workshop in Cambridge (UK) for contributing to this project.

Centering Meaning-Filled Design Within Engineering Education:
Recommendations on how to integrate interdisciplinary architectural design charrettes, community engagement, sustainability principles, and adapted Agile methodologies into a student-centered, project-based engineering program

Abstract
The Liberal Arts and Engineering Studies program (LAES) is a hybrid engineering and humanities degree housed in both the engineering and liberal arts colleges. LAES requires the same required math and science courses of standard engineering degrees, adding upper-level concentrations split equally between advanced engineering and humanities courses.

LAES was designed for retaining and recruiting a diversity of students in engineering, and to address recent innovations in industrial practice, technology design, and community-centered education. Through fifteen years of trial and error, the LAES program has developed a set of meaning-filled design guidelines for project work, combining engineering and humanistic problem solving with sustainable environmental practice integrated throughout every aspect of design, production, and use. In partnership with many departments across campus, especially Cal Poly's architecture program, LAES has worked on many projects that exist within the complex economic, political, social, spatial, and cultural needs of local communities.

LAES projects in collaboration with architecture students, have ranged from community housing construction with re-purposed shipping containers, to re-designing pedestrian neighborhood corridors, to the use of narrative-driven STEM education modules with underserved middle school students, to the design of immersive-reality explorations of artificial coral ecologies off the coast of California.

In this paper, we review what we have learned from our project work, with a focus on student learning assessment, leadership training, working across disciplines, and teamwork management, demonstrating how those practical academic concerns interact with the instruction of our design principles. We conclude by offering practical

recommendations for how other programs may use some of our design guidelines and project ideas within their own curriculums.

1 INTRODUCTION

1.1 Section 1 **University & Program Context**

The Liberal Arts and Engineering Studies degree at the California Polytechnic State University (Cal Poly) in San Luis Obispo is a hybrid BS program combining the study of engineering with the study of the arts and humanities. The program encourages students to see engineering, the sciences, and humanistic study as interconnected and as equally necessary for solving our planet's most important problems. LAES has the same entrance requirements as the College of Engineering at Cal Poly, thus requiring a strong grounding in physics and math, as well as the same writing, communications, history, culture, ethics, and reasoning requirements of the most demanding degrees in the College of Liberal Arts.

Based on continual student input and faculty guidance, the LAES Program has developed a number of popular hybrid concentrations that intermix engineering and liberal arts to create specializations in the study of sound and electronics; theater arts and computer game design; psychology and computer system development; art and aesthetics with industrial design; environmental stewardship with power systems management; community development with project design principles; and computer programming with technical communications. The LAES degree allows students to combine the most challenging aspects of the Colleges of Engineering and Liberal Arts at Cal Poly, while creating a hybrid study program that prepares them for their chosen career.

The LAES curriculum allows students to participate in multi-disciplinary development teams that work on real-world national and international technology and culture projects. To foster high-level leadership and communication skills, LAES student projects are always run in collaboration with other Cal Poly majors from Engineering, Liberal Arts, Architecture, and the Sciences, while working one-one-one with our program's commercial clients and partners from California and overseas. To further prepare students for the global marketplace and provide them with intercultural communication skills, the program strongly encourages students to spend at least one quarter studying or working abroad (LAES provides credit and partial funding for these trips).

LAES graduates have been highly successful in obtaining technical, design, and management careers in companies such as Warner Brothers Studios, Disney, Sony Pictures, Tesla, Apple, DTS, Universal Studios, Microsoft, as well as a wide range of high-tech and creative design companies throughout the world. The LAES degree has also served as the foundation for alumni who are currently pursuing graduate studies in MA, MS and PhD programs in psychology, engineering, social sciences, education, law, and business management.

1.2 Section 2 **Addressing Loss of Engineering Students**

The LAES program began as an attempt to stem the flow of Cal Poly students leaving the engineering college mid-way through their studies. At the time, well over 30% of the students who entered engineering as freshmen were changing to majors in the colleges of business, liberal arts, or science and math. Many of these dissatisfied engineering students chose to leave Cal Poly altogether, seeking engineering degrees at institutions that were less restrictive or in some way allowed for more productive integration with coursework from other disciplines. Engineering students who did not have the resources to start again at another institution or who could not afford to spend an additional two to three years to complete a new degree at Cal Poly decided to stay in engineering, resulting in lower grades, and overall dissatisfaction with the institution.

After a year-long, multi-level university proposal review process, the pilot LAES program was fully adopted into the Cal Poly curriculum as a BA program in 2013. The program continued to expand its number of students, roughly doubling in size between 2013-2018 (from 25 to 80 students). In 2017, in response to persistent student requests and requests from the employers of LAES graduates, the program changed from a BA to a BS degree to more properly represent the extensive scientific and technical aspects of this hybrid degree.

The creation of the LAES program, more cross-program collaboration between engineering programs, and a related, open-structure revision to the General Engineering program have often been credited with greatly reducing this loss in Engineering students at Cal Poly. In this paper, we examine some of the key features of the LAES program's design that we believe are central to helping retain and improve the overall academic and professional success of good, interdisciplinary Engineering students, while also adding a more community-focused, principle-driven aspect to Engineering study and practice. The full history of the program's development, along with a discussion of the organizational and divisional differences that had to be overcome the creation of this kind of hybrid program between two different colleges, can be found in this article:

'When the hurly-burly's done, of battles lost and won: How a Hybrid Program of Study Emerged from the Toil & Trouble of Stirring Liberal Arts into an Engineering Cauldron at a Public Polytechnic," Engineering Studies, 2014.

1.3 Section 2 **Project-Based Learning Trial, Error, Assessment & Review**

During the first few years of the LAES program's trial run, all the faculty, administrators, and students connected to the program engaged in much trial and error to determine the most effective methods for bringing together students with diverse LAES academic concentrations to work complex projects that needed to produce a set of useful deliverables for real-world clients. At the same time, the LAES program was also experimenting with how to partner with other academic programs for short- and long-term engagements on the same project, with design and development work that often spanned many quarters.

Throughout this process the program conducted many informal and formal assessment processes that ranged from student consultations and surveys on group work management and grading, to end-of-process review of project deliverables with project clients and LAES program academic advisors, to examining how some end products fell short of expectations and where others met expectations and goals or greatly exceeded them. These assessments all resulted in action items that were then integrated back into the program the following year to serve as additional points for continuing, long-range review, revision, and implementation.

Over the last ten years, these ongoing assessment processes have informed continual changes (large and small) in the program's core course structures, the selection of each year's project partners, the effective management of student teamwork, and the continual refinement of the grading process. The yearly internal (Cal Poly and CSU) assessment processes were then reviewed and amplified further as the program moved from the trial-run phase to full program phase as a BA, then through a comprehensive series of external reviews, and yet one more program review for the conversion of the program into a BS degree.

These three additional external program reviews (trial-run, BA, BS) involved analysis of changes in student demographics, academic achievements, writing assessment based on randomly selected student senior project essays and documents, student and project client surveys, surveys of potential and actual student employers, alumni surveys, and continual consultation with LAES student leaders to help develop new study concentrations for the degree. The external program reviews were conducted by program directors and academic administrators from other engineering programs around the country including the Massachusetts Institute of Technology (MIT), the Colorado School of Mines, Rensselaer Polytechnic Institute (RPI), Union College, among others.

All the review and assessment processes commented on the program's successful integration of community and client-center projects, charrette-inspired iterative design, and structure for our projects, and the effective use of agile and scrum methodologies in the management of our project-based learning capstone courses and for project/client work. Additionally, over the last ten years of the program's existence, we have integrated a few basic environmental sustainability principles into every project we undertake and have developed program specific meaning-filled design principles. We will now briefly discuss how we put these methodologies and principles to use with three projects chosen from the beginning, middle and current state of the program.

One of our main sources for pedagogical inspiration comes from Schon's work, "Educating the Reflective Practitioner" (1987) in which he says:

"Designing, both in its narrower architectural sense and in the broader sense in which all professional practice is *design-like*, must be learned by doing. Though students may learn about designing from lectures or readings, there is a substantial component of design competence—indeed at the heart of it—that they cannot learn in this way. A *design-like* practice is learnable but it is not teachable by classroom methods. And when students are helped to learn design, the interventions most useful to them are more like coaching than teaching—as in a reflective practicum."

Schon continues by noting that "…professional education should be centered on enhancing the practitioner's ability for "reflection-in- action"—that is, learning by doing and developing the ability for continued learning and problem solving throughout the professional's career. If knowledge in the professions is advanced through this process of reflective practice, successful education of students learning the profession should be centered around opportunities to solve real problems involving multiple approaches and to repeat the process of trial, critique, and reflection often." (Schon 1991)

2 METHODOLOGY

2.1 Section 1 **Community & Client-centered Projects**

Over the ten-year span of the LAES program, we have worked on well over forty different projects, large and small, some running only a few months, others running for many years. These projects are all quite different from each other, often with very different clients and deliverables. However, they all share the same organizational, design and implementation principles.

We have chosen three projects to use as examples in this paper, all of which have and additional shared element of collaboration with the architecture program students and faculty at Cal Poly. These projects also are all centered around community education and civic engagement.

The **HO:ME** project (Housing Opportunities Through Modular Environments; 2009-2010) was a LAES design and development project in collaboration with the Cal Poly Architecture program, and the Housing Authority of San Luis Obispo (SLO). The project worked to design and then have approved for development, a transitional housing facility for the city of San Luis Obispo, built from repurposed shipping container materials, to assist residents transitioning from an unhoused situation into community supported housing situations managed by the SLO housing authority.

The **Two-Towns** project (2015-2017) was a LAES design, development, and user-testing project in collaboration with the Cal Poly Architecture program and various civic and business organizations for the city of Sacramento. This project worked to design, develop, and then test the efficacy of various ways to encourage more public use of a large pedestrian passageway connecting an older commercial part of downtown Sacramento with a newer entertainment complex. The project eventually focused on the use of augmented reality systems to help visitors explore and better understand the artwork and historical displays installed throughout the length of the passageway, thereby also learning more about the history of the structures, land, and communities of California's capital.

The **Ocean Sight One** project (2022-Ongoing) is a LAES design, development, and public education project in collaboration with the Cal Poly Architecture and Music programs and a marine research center at the University of California Santa Barbara (UCSB). This project is developing new forms of immersive visual and aural presentation to take citizens of California into the vibrant artificial coral reefs that have developed at the base of the oil rigs off the coast of Santa Barbara. These rigs are soon due to be decommissioned and, in some fashion, removed. The marine life at their base constitutes some of the most healthy and robust coral environments in the world, environments that many people want to preserve and expand upon.

Ocean Sight One aims to educate the California public about the history of these oil rigs, the complexities of the decommissioning process, the state's connection to this process, the importance of maintaining healthy coral reefs, and the inter-connections between the natural elements of these reefs and the built environments of the rigs which were created for industrial use. The project will develop, test, and then present in various public formats immersive 3D cinematic experiences, mobile virtual-reality, and augmented-reality interactive games, all built from underwater 360 high-quality video and audio captured from deep ocean dives around one of the central Santa Barbara oil rigs engaged in this process.

2.2 Section 2 **Charrette-inspired Iterative Design & Whole-Systems Thinking**

The use of the term word Charette is said to originate from the École des Beaux Arts in Paris during the 19th century, in which instructors circulated a cart (a "Charrette") through the studio, collecting final drawings while students frantically put finishing touches on their work. The work was quickly critiqued, and the process began again building from the positive elements of the most recent critique. A variation of this charrette form of rapid iterative design has long been a key part of Architecture practice and education, but in the last twenty years charrettes have become a part of many design disciplines. We have adopted the use of charrettes to initiate the work on many of our projects in LAES, especially when those projects connect to the Architecture program.

The iterative design methods and compressed design/review/revision structure guides all our work in the LAES program. For example, in collaboration with the Architecture program, for the Two Towns project we used a series of design charrettes with students and local community to develop the visual, interactive, and rhetorical approaches we would take with our design work for the city of Sacramento. The charrette briefs distributed to student teams at the start of the charrette required that all the charrette's design iterations (in accordance with the federal building guidelines from the Americans with Disabilities Act—ADA) account for accessibility issues in their designs (designing for visitor differences with hearing and seeing abilities, height, wheelchair use, language, and age).

This design requirement to account for public accessibility has become a central requirement for all LAES projects, teaching students to empathize with how different people and communities will engage with the technologies and systems they create. In their accounting for ADA guidelines in all their work, engineering students must also research, discus and resolve in their final design issues of inclusion, diversity, equity, ethics, psychology, and civic governance alongside their concerns for safety, efficiency, and effective use of materials.

We have found that this whole-systems form of thinking requires the LAES students to make active use of their studies in liberal arts as much as their study in engineering and the sciences. This inter-linkages of concepts between disciplines through hands-on practice and team-centered discussion, we believe forms the core educational purpose of our de-centered capstone courses in which students teach themselves as much (if not more than) the program and our faculty teach them. (Muscatine 2009)

2.3 Section 3 **Agile & Scrum Production Methodology**

Agile is a methodology for software development that emphasizes flexibility and collaboration between cross-functional teams. (Beck et all 2022) It emphasizes iterative development, continuous feedback, and adapting to changes as they arise. Scrum is a specific framework for implementing Agile principle and values in product development. (Sutherland 2015) It defines specific roles, events, and artifacts that help teams work together efficiently and effectively. It involves a series of sprints, lasting two weeks each in our courses, during which the team focuses on a particular set of features or functionality deemed most important to the customer to grow the working product increment in a way that maximizes the return on investment. At the end of each sprint, the team presents its completed and tested work to all stakeholders who collectively decide which work items to keep, change, or remove. This activity is called a Sprint Review.

Our students use Scrum to complete work for our collaborators. Scrum keeps the student teams communicating and working together effectively while remaining consistently focused on customer satisfaction. The testing requirement of the Sprint Review improves the quality of student deliverables while its live demonstration of working functionality component drives customer feedback and involvement. The scope of work completed, thoroughness of testing, presentation quality, and rate the stakeholders approve of work provide regular opportunities for individual and team learning assessment to guide our course grading.

2.4 Section 4 **Project Integration of Environmental Sustainability Principles**

Many of our projects in LAES are not lavishly funded, and often function with almost no funding at all. Therefore, from necessity, the program focuses on frugality and recycling. As a result, the program has adopted a cradle-to-grave-to-cradle principle for all project purchasing and equipment use. But we also require students to demonstrate how they have used the cradle-to-grave-to-cradle principle with their project designs and recommendations for future iterations of their project solutions.

The overall goal of focusing on continual re-use and re-creation with our project and design materials is to, whenever possible, divert our materials from becoming an immediate addition to the waste stream of the community. This was demonstrated in the HO:ME project by the very nature of the materials we were proposing to be used for the city's housing project—shipping containers which have become a blight for many countries where they are discarded into vast waste dumps once they are deemed no longer viable for use in containerized shipping.

HO:ME project students worked with the city of San Luis Obispo, to convince the local community that these re-purposed containers of steel and wood could provide effective, aesthetically complimentary material for construction at a much lower cost than working with less sustainably sourced building materials. Two Towns project made use of existing artwork and informational materials in the passageway, and a connection with the smartphones of visitors to not only create newly expressive and interactive "materials" for the space, but also to educate visitors about the history of these artists who created the work (the Royal Chicano Airforce). These artists designed their work to function at two levels: one level had a hidden cultural history embedded within each mural which was accessible to those who knew of the artists intention and symbology prior to viewing, and a second level designed to teach all visitors about the agricultural practices and migrant labor communities connected to the city of Sacramento.

While the Ocean Sight One project is still in early process, the entire focus of the project is on large-scale sustainability issues that involve the preservation of robust marine environments that are intimately connected with the repurposing of industrial construction and drilling materials. The media aspects of the project also work to make extensive use of prior-gathered site images, sound recordings, and site data for presentation in a new format designed to instruct larger state audiences about the sustainability decisions the state will be making on their behalf in the coming years.

2.5 Section 5 **Project & Program Integration of Meaning-Filled Design Principles**

As a result of ten years of work with charrettes and agile, in conjunction with creating products and solutions for different clients and communities we have arrived at a set of design principles that we call meaning-filled design. We require all students to address these principles, in some substantial way, with every part of work on an Agile development team, with their collaborative work in a charrette process, and with the development of their individual senior projects.

These design principles evolved from the actual construction and implementation of our projects in actual public locations, through interaction with visitors, audience members, and other people in a community. Actual use, by humans, of our design decisions in human communities immediately **gives meaning** to our project deliverables, inventions, and overall solutions, with all the complexities (ethical, moral, symbolic, communicative) that come with this use-generated semiosis. Therefore, when working in community-centered contexts, our students can not only design for technological and mechanical efficiency and effectiveness but must also design for **human-centered meaning** that arises from use. We say their work is meaning-filled, in that they are aware that through public use, every aspect of what they create will be invested with meaning as it enters its use community, therefore it is meaning filled.

These meaning-filled principles, at one time or another, serve as the basis for nearly all our program review processes and are key points for discussion with senior students as they develop their senior project, capstone projects.

These design principles are:

1) **Build for and with community**, appreciating and integrating local symbols, signs, stories, and history into your work.
2) **Extend empathy** throughout design by understanding and accommodating difference.
3) **Encourage critique** through open collaboration and iterative participatory revision.
4) **Embrace complexity** while working toward simplicity.
5) **Establish trust and transparency** through extensive user testing and critical engagement.
6) **Be inclusive** in all discussions, designs, implementations, and public use.

A full discussion of these design principles and their application in our program would require a much longer paper to cover in depth. We introduce these principles here for consideration by other engineering programs that may be asked to become more community-focused and inclusive in their pedagogy but lack curricular methods to address these concerns within a more traditional engineering curriculum.

Instead of trying to address these issues by simply requiring engineering students to take a course in ethics, or community development from other disciplines, we recommend that choosing community-based projects as the center-pieces of problem solving and design within a project-based learning engineering course, can be a way to bring to the fore concerns for empathy, inclusion, diversity, difference and communication while at the same time putting to use standard engineering problem solving for the technological and mechanical aspects of the solution. (Sneider and Zhu 2020)

The three projects referenced above (HO:ME, Two Towns, Ocean Sight One), required engineering expertise and problem solving to be effective, but that engineering work could not stand separate from the equally compelling liberal arts concerns dealing effectively and fairly with community histories, needs, and interests.

3 RESULTS

3.1 Section 1 **Adapting to Diverse Student Needs & Diverse Demographics**

Diverse projects working with diverse communities provide a diverse collection of students many ways to personally connect with the work at hand and allows them to connect what they are producing as students and learners with their lived experiences from outside academia and their roles as citizens in a global community. We believe the program’s focus on diversity in every aspect of design, instruction, and community engagement has made the program welcoming to students who may have otherwise felt their full set of interests and lived experiences were not considered relevant within an otherwise more traditional, fundamentals-only engineering curriculum. (Lehr and Haungs 2015)

When surveyed over the years, by external program reviewers and through internal program assessments, current and recently graduated students comment on how the integration of engineering and humanities disciplines made them better communicators, collaborators, and more active members of their community. These findings were summarized, in one external program assessment (2012) by the lead reviewer from MIT who noted:

"Our site visit…made it clear that student retention at Cal Poly was one of the most admirable achievements of the LAES program. LAES currently serves as a "retention net" (as distinct from a "safety net") in serving to retain some of the brightest, creative, self-driven and entrepreneurially minded students who were formerly enrolled in an engineering degree program at Cal Poly…it should be noted that the program contributes not only to the general problem of retention, but to the specific problem of retaining women, minorities, and socioeconomically disadvantaged (and as it turns out, privileged) students who feel overly constrained by a traditional engineering degree program…(surveyed students) reported a separate passion, for music, for computer graphics, for law, for global economic development—areas of study that maps onto the disciplinary mix generally found within the College of Liberal Arts."

3.2 Section 2 **Learning Assessment Using Agile Adapted to an Educational Setting**

The events and artifacts defined by the Scrum framework provide natural points in production to integrate academic grading, specifically Sprint Reviews. This has two main advantages: grading efficiency and increased student engagement. The grading process is more efficient because there is no need to introduce extraneous artifacts such as quizzes, exams, or written reports. We use a grading rubric that measures the following criteria of a Sprint Review: scope of completed work, work items accepted, testing, demonstration, professionalism, individual review, and publishing materials. The use of Sprint Reviews not only provides a consistent method to incorporate stakeholder feedback it also provides consistent feedback to each student regarding course performance.

The Scrum framework also increases student engagement. At the beginning of each Sprint, each team is empowered to select the scope of work they will complete during the sprint. They make these choices considering the skillsets of the team, available resources, and stakeholder requirements. This gives them direct influence over their own learning assessment while providing real world services to community partners. Our use of Scrum fits naturally into any course that strives to focus on project-based learning, such as in a cornerstone, capstone, or senior project experience. Scrum seamlessly provides team management, a clear production schedule, customer feedback, and opportunities for academic assessment that is widely used in industry.

Summary

While building a hybrid engineering and liberal arts program like LAES might not be possible at other institutions due to structural, political, and disciplinary impediments (Vanasupa et all 2012), we believe that many of the design and instructional principles we have developed and refined over the years can be adopted in piecemeal to help diversify, strengthen, and positively amplify attempts to better connect engineering education with the communities of students and civic/commercial organizations that it serves.

ABSTRACT

In some Spanish universities in recent years, there has been a decrease in the number of students, mainly due to the drop in the birth rate and the increase in the number of universities throughout the country. In addition, the number of (unknown)bachelor's degrees that can be studied at university has also increased.

For these reasons, since 2010, an activity called Campus Praktikum has been carried out at the Universitat Politècnica de València to bring the university studies taught at this centre closer to secondary school students. The aim is to show the studies taught at the UPV (mainly engineering studies), to find out about the professions linked to these studies and to be able to have testimonials from university students who are currently studying. During one week, secondary school students take part in

[1] *Corresponding Author*
E. Giménez-Carbó
esgimen@cst.upv.es

workshops related to university studies, which give them an in-depth understanding of the content of their studies and university life.
The main objective is to increase the number of students in general and, above all, to increase the number of women who choose the UPV for their university studies.
The paper describes what the activities of the Campus Praktikum consist of and compares the opinions obtained through surveys of students who enjoyed the activity right after finishing the campus and the information obtained from the student's registration at the university.
With all this information conclusion will be drawn, analysing the actual effect of this type of activity on the student's choice of university studies.

1 INTRODUCTION

Over time, the number of universities in Spain has increased significantly. When the Universitat Politècnica de València (UPV) was established in 1968, there were only 18 universities in Spain. By 1990, that number had grown to 40, and as of the 2020-21 academic year, there are now 84 universities in Spain, with 50 of them being public and 34 private (Ministerio de Universidades, 2022), (Rodriguez, 2017).

This rapid growth in the number of universities has led to diverse academic programs and study locations, creating a competitive environment for universities. To attract the best students, universities must take action to publicize their programs and campuses. To address this challenge, the UPV launched the Praktikum Campus in June 2010, initially as a pilot experience at the Higher Technical School of Industrial Engineering. The program has since expanded to include all schools, faculties, and campuses of the UPV.

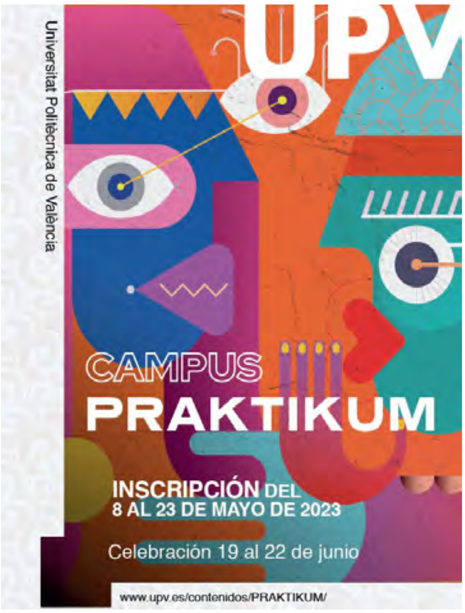

Fig. 1. Image and poster of Campus Praktikum 2023

The Praktikum Campus is designed for high-performing students in their first year of the Baccalaureate or Higher Degree Format Cycle (in Spain, young people finish compulsory education at the age of 16. Subsequently, students who wish to pursue university studies take the baccalaureate, which consists of two preparatory courses for university entrance). Participants can attend workshops and activities organized by UPV teachers and researchers and experience campus life first-hand.

The Campus Praktikum aims to promote different degrees offered by the UPV, attracting students and making the university their choice for higher education. The paper describes the selection process, workshop assignments, and preferences based on gender.

Additionally, it explores the different activities during the week-long Praktikum Campus and the feedback gathered from participants.

At the time of writing, registration for the Campus Praktikum 2023 is open (Figure 1).

2 METHODOLOGY

2.1 Which students can participate

The methodology section of this paper outlines the various aspects considered in developing Campus Praktikum 2022. The Praktikum Campus programme has grown from a single school and project in 2010 to 33 projects in 2022 across 11 schools and two faculties. The projects that will be part of the Praktikum Campus will be published on the UPV website[2] in May, and the opening of registration for first-year baccalaureate or vocational training cycle students will be publicised. Secondary education institutes and training cycles are also contacted via email, explaining the Campus and encouraging centres to invite the best students.

To partake in the program, both the student and their high school must take note of the following recommendations and requirements:

Student Requirements ; To be admitted, the student must:

- Be in their first year of a baccalaureate or vocational training cycle during the 2021-2022 school year.
- Have completed all areas and subjects during the school year.
- Provide an academic certificate from their high school that displays their average for the first and second terms.
- Participate actively in various activities at the Campus Praktikum 2022 UPV. (It is anticipated that this will require approximately 25 hours spent at UPV.)
- Complete the evaluation and satisfaction surveys after the program.

Recommendations for the student's school include:

- Each high school should disseminate information about Praktikum, taking into account the minimum average grade required for admission to the Campus in previous editions.
- Please keep in mind that for the Praktikum 2022 program, three students from the same Center will be chosen. However, any number of candidates may apply as appropriate.

Students who wish to join campus activities should indicate which projects they would like to participate in, ranked in order of preference, and provide a certificate of their grades from the first and second evaluations. Selection for the program will be determined by both grades and project preferences.

2.2 Description of Campus Praktikum activities

Throughout the week of the Praktikum Campus celebration in 2022, high school students were present at one of the UPV campuses (Vera, Gandía, and Alcoy) from 9:15 am to 5:00 pm, engaging in various morning and afternoon activities as detailed in figure 2's schedule.

The aim was not only to introduce students to the degrees offered at UPV but also to expose them to the broader university experience. In total, 33 projects were available during this year's call, linked to 40 degrees across the three UPV campuses, as seen in figure 3's list of projects.

The workshops, primarily in labs, encouraged hands-on learning, with UPV faculty and staff providing activity proposals (Figure 4). At 2.00 pm, students took lunch breaks and could ask questions and receive information from current UPV students.

3 RESULTS

The Praktikum Campus 2022 was a successful event that fully satisfied all participants, and students were delighted upon completion. To better gauge the extent of satisfaction and identify areas for improvement in the program, 203 students completed an eight-question survey. The questionnaire included inquiries about the campus organization, such as the dates and duration of the event, and questions specifically regarding projects, such as the level of satisfaction (Figure 7) and whether participation influenced their university studies choice (Figure 8).

Fig. 7. Are you satisfied with the project you have been involved in?

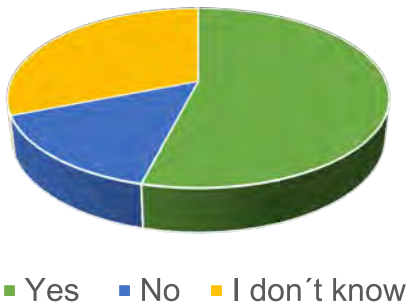

Fig. 8. Do you think your participation in Campus Praktikum will influence your choice of stuides?

Furthermore, a Likert-scale question was posed to get feedback on each student's project (Figure 9). Conversely, the level of participation in the workshops has been inconsistent when viewed through a gender lens. In the highly sought-after 1 Biotechnology workshop, all selected students were female, and the minimum average grade required to participate was 9.5 out of 10. However, in computer science-related workshops 13 and 14, over 90% of selected students identified as male.

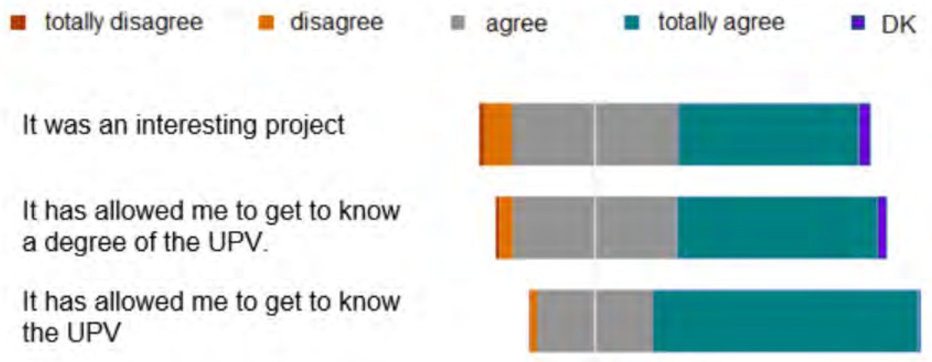

Fig. 9. Students´ opinions about the project they have participated in

This gender trend is also reflected in undergraduate classrooms. Workshops 1, 10, 22, and 23 had the most female-identifying students, with percentages ranging from 100% in Workshop 1 to 65% in Workshop 10. Conversely, most students in the remaining workshops identified as male, with workshops 6, 9, and 15 being exclusively male. In addition, two open-ended questions were posed to students regarding their intended studies and their opinions of the Campus.
A study has also been launched to determine which students participate in the campus praktikum, and who subsequently choose the UPV as the university to do their degrees. Due to the suspension of activity in the 19-20 and 20-21 academic years by COVID, only the students who participated in the Campus Praktikum in the 18-19 academic year began their university studies in the 20-21 academic year could be known. The results (Figure 10) show that 55% of the students chose the UPV. Moreover, there is a great variety in the chosen studies (Figure 11).

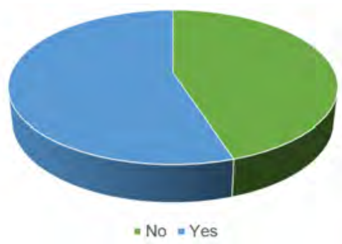

Fig. 10. Students enrolled at the UPV after the Campus Praktikum

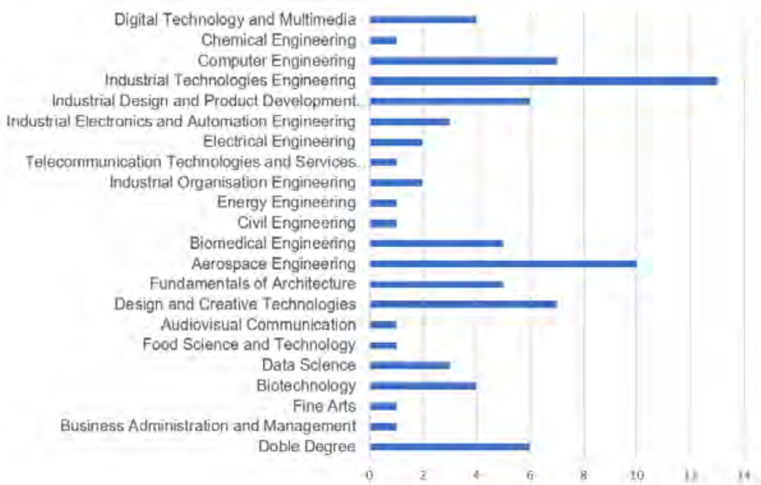

Fig. 11. Studies chosen at the UPV by Campus Praktikum participants

4 SUMMARY AND ACKNOWLEDGMENTS

As a summary of the work it can be said:

- Participation in the Praktikum Campus positively impacts students, and 96% express their total satisfaction with their participation.
- It should be noted that all the personnel involved in the preparation and delivery of the workshops of the projects do so voluntarily, without receiving any financial compensation.
- However, the most remarkable result is that 54% of the participants have indicated that their participation in the Praktikum Campus will influence something as crucial as selecting their university studies. Only 31% indicate that this activity does not affect this decision.
- Primary and secondary schools must continue to work to motivate girls to become interested in STEAM studies. It is essential to show models of women who have followed this type of study and not lose the talent of half of the population, which for some reason, prefers not to follow this type of study.
- It is essential to carry out this type of action to bring universities closer to their future students so that they get to know each other and help them choose the studies that will bring them closer to the professionals they will be in the future.

It is foreseen that in the coming years the activity will continue, and the results will continue to be analysed to optimise its content and ensure that as many students as possible get to know the UPV.

The authors would like to thank everyone involved in the realisation of the Praktikum Campus for their dedication to the project and, above all, the students whose enthusiasm encourages us to continue with the task.

ABSTRACT

Continuing engineering education (CEE) is becoming an attractive notion of continuously enhancing and upgrading the engineering skills required by the Fourth Industrial Revolution. Current developments in science and technology and the challenges to address the United Nations Sustainable Development Goals (UN SDGs) of the 2030 Agenda require updating theoretical knowledge, skills, and specific practical work. Even though higher education institutions (HEIs) can provide CEE or CPD (Continuing Professional Development) within or external to degree programs, CEE focuses on training engineers as lifelong learners to meet societal and industrial needs. A comparative study was conducted among eight universities to analyse the strategies used to provide CEE services at an institutional level. This study aims to investigate approaches and practices in CEE offerings to learn lessons and adjust CEE programs and policies in the HEIs involved in this research. The study followed an adapted version of a Comparative Case Study (CSS) as a suitable framework to map the CEE strategies and approaches of the participating universities. Preliminary results indicated differences in the organisational structures, e.g., traditional courses within existing programs. At the same time, other institutions provide flexible mechanisms such as short courses, modules, or micro-credential activities leading to qualifications. Similarities are found in institutional policies aiming at developing postgraduate programs aligned to industry demands. This study reflects the importance of learning programs as resources provided by HEIs applying a framework for engineering education and the engineers' further professional development.

1 INTRODUCTION

There are many drivers for change in engineering education, such as Industry 4.0, Artificial Intelligence, Digital Transformation, or responding to the Global Grand Challenges, such as the UN Sustainable Development Goals (UNESCO 2021a). Quite rightly, research is focused on how we develop the required competences for emergent engineers through university studies, including a mixture of technical expertise, such as in reconfigurability (Andersen & Rösiö 2021), digital skills and data management (Sharipov et al. 2021) and transversal skills, such as socio-cultural/intercultural competency (Boyadjieva &Ilieva-Trichkova 2023), as well as in leadership, interpersonal skills, ability to work efficiently in teams, managing interdisciplinary teamwork, communication skills and change, amongst others. However, these challenges equally require examination of the developmental needs of practising engineers and engineering educators, so that Continuing Engineering Education (CEE) practices are developed to meet these needs. Therefore, for this study, CEE is considered to be the additional education of a practising engineer or technologist/technician after an initial recognised phase of education, typically an undergraduate degree (Uhomoibhi & Ross 2019).

The area of CEE is comparatively under-researched, and there is a lack of contemporary publications around the practices and models within institutions concerning CEE. It is this gap in the extant literature that this research seeks to address, by comparing the institutional practices of eight Higher Education Institutions (HEIs) in eight different countries. This comparative case study will outline what institutions are doing and how they are approaching this. The objective is to capture how CEE is developed and implemented within differing institutions to determine any similarities and differences with the intention to inform enhancements to institutional policies and practices. Also, the differences among these institutions in the level of CEE offerings and approaches can serve as an inspirational source for others to start developing CEE activities in their own organisations. Moreover, we aim to learn from and inspire each other's developments. Consequently, the research question for this study is 'What are the approaches at institutional level to integrate Continuing Engineering Education policies?' As all institutions offer full, taught postgraduate programmes, this research will focus on other forms of CEE offering.

This paper will first outline the context of CEE in Higher Education, briefly introducing the eight institutions in this study, before detailing the comparative case study methodology adopted for this research. Next, the study offers comparative findings around how CEE is organised and resourced, what do institutions offer as CEE, the level of involvement of industry in what is offered distinctive aspects found in institutions. Finally, we discuss next steps and future directions in this comparative research.

2 CONTEXT OF CONTINUING ENGINEERING EDUCATION IN HIGHER EDUCATION

Continuing Engineering Education is an essential aspect of any professional engineer maintaining the required competences to practice, whether this be to stay current with new emergent technologies, or develop new skills, e.g., around sustainability or in change leadership (International Engineering Alliance 2021). Nowadays, there are a range of learning modalities for engineers to develop such practice - through experiential learning, through non-formal learning or through formal learning, or learning-on-the-job (Lynch and Russell, 2009). Additionally, there is also a diversity of providers, from internal training courses and mentoring, online courses, to training organisations, to courses from Original Equipment Manufacturers and Technology/System Providers', as well as a range of offerings from educational institutions, both further and higher education (UNESCO 2021b). This complementary eco-system of providers enables the required flexibility for individuals and their organisations to organise their CEE offers.

HEIs have played a long-standing role within this CEE landscape, particularly in the provision of postgraduate/Masters qualifications, at the research-teaching and research-praxis nexus. However, the greater diversity of learning options and immediacy of access to some forms of learning, makes it important to examine how HEIs are responding to those demands, and to see if there are similarities and differences between the different forms of HEI: public university, private university, technical universities, commercial (for profit) providers. This research adds insight into how HEIs are organising themselves in response to these needs, as well as highlighting how the different types of courses and how these educational offerings are developed (e.g., driven by market, knowledge sharing by HEI, or in collaboration). As all institutions offer taught postgraduate programmes, then the research will focus on other forms of Continuing Engineering Education offering. The focus on just a sample of HEIs is acknowledged as a limitation of this research.

The eight (8) institutions involved in this research are from eight different countries, seven of whom are European (see authors' institutions above), with examples of CEE offered (Table 1). They represent a range of different HEIs across the forms outlined in the paragraph above, and all engage within a range of CEE activities, whether that be offered internally (to students and staff) or for external provision. The fact that the participating institutions are from different countries provides a breadth of approaches. However, it is acknowledged that the institutions are not necessarily representative of these countries. Additionally, the institutions also are at different points in the lifecycle of adapting their CEE provision; this research is not focused on evaluating competitive positioning rather to determine if there are shared aspects that are influencing the decisions on policy and practice.

Table 1. Participating Institutions and code use for results below

Institution	**Code**	**Example of CEE provision offered**
Aalborg University www.aau.dk	A	Short courses/modules, Master programs (MBA) eg within Cyber Security and Privacy, Management of Technology, Building physics, Circular economy, Energy efficiency
Aalto University https://www.aaltoee.fi/en	B	E/MBA programs, long and short courses, micro-credentials, modules, customised programs, online programs. Themes from all six Aalto University schools are represented.
TU Berlin www.academy-tu.berlin	C	Degree programs (MBA, MBL, MSc) and short courses in the areas of Data Science, Sustainability, Management & Leadership, Engineering & Mobility

Tecnológico de Monterrey https://tec.mx/en	D	Degree programs (MBA, MBL, MSc) and short courses in the areas of Business Analytics, Cybersecurity, Biotechnology, Data Science, Applied Artificial Intelligence
Glasgow Caledonian University https://www.gcu.ac.uk/study/part-timestudy	E	Short courses, e.g. in Data Analytics & AI Machine Learning; Renewable Energy Technologies; Climate Change & Carbon Management.
Uppsala University - The Faculty of Science and Technology https://www.uu.se/en	F	Short courses in, e.g. Industrial analytics, Sustainable energy transition, Biomaterials, Additive manufacturing in metallic and ceramic materials, Application of augmented reality in industry, Data mining, Statistical machine learning, Self-leadership etc.
EPFL https://www.epfl.ch/education/continuing-education/	G	Degree programs (COS, CAS, DAS, MAS) and short courses around science, technology and engineering (i.e., Data Science, Machine Learning, Supply Chains, Fintech, IOT, Geoengineering, Risk Management, Urbanism, etc.)
TU Eindhoven https://www.tue.nl	H	Short courses on a variety of topics, e.g. mechanical engineering, etc.

3 METHODOLOGY

The nature of the research question is descriptive and exploratory, so is best suited to a qualitative methodology. Specifically, a comparative case study approach has been taken, adapted from Barlett and Vavrus (2017). A purposive sample of institutions was selected to participate in the study with inclusion criteria being that each institution had some involvement in Continuing Engineering Education; this sampling strategy is recognised as a limitation of the paper, but in this exploratory research a purposive sample is appropriate, as the study seeks to identify factors that influence policy and practice around CEE.

Data collection was achieved through each institution completing information against a standardised set of criteria. These criteria were generated based on factors that covered meso (institutional) level and micro-level (programme and course) factors. Meso factors covered: how policies supported CEE; organisational structure; ease of CEE operating within regulations; permitted offerings (type of courses & provision areas); university systems to support; resourcing (staffing) approaches; teaching, learning and assessment methods. Subsequently, each institution summarised the pertinent aspects that related to the research question into a short (one to two page) institutional summary.

An inductive, group analysis of the detailed and summarised institutional cases was conducted to determine shared practices, similar factors influencing policy, practice and decision making, as well as potential differences. The findings of this comparative analysis are presented below.

4 FINDINGS AND DISCUSSIONS

Based on the collective and comparative analysis of the eight cases, then three main aspects were identified: 1) how each institution organised the provision of CEE, including how it resourced such courses; 2) what courses were offered and how did these fit into any flexible qualification provision, and 3) how strongly were the offerings aligned to the needs of the market (including whether the courses were co-designed between a HEI and another organisation).

4.1 Organisational structure and resourcing

Seven of the institutions arrange some (or all) of their CEE offerings from within the institution's existing organisational structure, whereas in one institution (#C – TU Berlin) then this is solely arranged through an associated private company (APC) (Table 2). As an APC is also a form of centralised offering (owned subsidiary of one or more than one institutions), then seven institutions use a centralised approach, reflecting the importance of having strategic vision and policy enactment for CEE, and seeking to use centralised services (such as finance). De-centralised offerings reflect either ad-hoc opportunities, or a decision for continuing education to be more focused in particular schools and faculties. Drivers for different forms of supporting organisational structure relate to national legislation, flexibility, and building from a school/department outwards, with macro factors (legislation, government policy) being a significant driver of institutional policy and decisions.

Table 2. Organisational approach to offering CEE.

	A	B	C	D	E	F	G	H
Associated private company/ foundation		X	X	X	X		X	
Centralised CE offering	X	X	X	X	X		X	X
De-centralised CE offering	X	X				X	X	X

An interesting aspect of CEE between the institutions is differing practices around how these offerings are resourced (Table 3). Six institutions are able to use institutional staff within their existing contracts, but for two institutions (#B – Aalto University, #C – TU Berlin), then they have to remunerate lecturers additionally for their involvement. These two institutions also use APCs, reflecting policy and legal requirements within their institutions/countries. Discussions highlighted that resourcing is a key area of policy and enactment of that policy that enables effective CEE offering.

Table3: how CEE offerings are resourced

	A	B	C	D	E	F	G	H
Institutional staff - within contract	X			X	X	X	X	X
Institutional staff - paid		X	X	X	X	X	X	
External to institution staff - paid	X	X	X		X	X	X	
Partnership with external institution		X		X			X	

Of note, all institutions do not subsidise the running of courses, with the costs being met through a variety of means, including government, commercial or individual funding; the balance of sources of the above funding varies between institutions.

4.2 Types of CEE Offering

All institutions offer full taught postgraduate programmes (as outlined above), so these are not considered in these findings. Table 4 indicates that all partners are engaged in a range of courses – from stand-alone Continuing Professional Development (CPD) modules, to up- and re-skilling, up to full Masters programmes (delivered through APCs, or through credit stacking in a more flexible way). These offerings can be non-credit bearing, or carry credits. For those offerings with credits (for example micro-credentials), then these could be stand-alone or institutions may offer a structure or flexible pathway to a university qualification. Some institutions (#B – Aalto University, #C – TU Berlin) have to clearly distinguish between what their institution offers as Masters degrees and CEE offerings, due to legal frameworks in their respective countries.

Table 4: Types of CEE offering

	A	**B**	**C**	**D**	**E**	**F**	**G**	**H**
Masters (EQF7) programme	X	X	X	X	X		X	
Open course	X	X		X	X	X	X	X
Closed course	X	X	X	X	X	X	X	
Bespoke (*tailor-made*) course	X	X	X	X	X	X	X	X

The majority of the courses offered are to those outside the institutions, such as practising professionals. However, in the discussions (and not reported here) was also the importance of CEE to support staff development, and this is a potential area for future research.

4.3 Engagement with industry and organisations

All institutions have a strong market alignment (Table 5) that demonstrate market awareness and offering relevant qualifications, either through partnership (through co-creation) or through being market-responsive are essential aspects of successful CEE offerings. Additionally, as would be expected within a university, then all institutions offer courses driven from their expertise. Courses are not just for commercial organisations, but are offered for public organisations, and can be commissioned. Amongst institutions co-created courses are still less frequent, reflecting the enhanced co-ordination and co-operation to generate such courses.

Table 5: Market alignment of CEE offerings

	A	B	C	D	E	F	G	H
Market-driven/specified	X	X	X		X	X	X	
University-driven/specified	X	X	X	X	X	X	X	
Co-created	X	X	X	X	X	X	X	X

5 SUMMARY AND FUTURE DIRECTIONS

This comparative study has compared how eight different Higher Education Institutions are approaching Continuing Engineering Education using a comparative case study framework approach. Whilst, the institutions are at various stages of evolution in terms of offering CEE, some have done so for decades, whereas others are newer in this area, then key similarities emerged: broadly a centralised, approach to CEE, with a clear strategic vision that creates clear CEE offerings that are aligned to the marketplace. Differences, such as Associated Private Companies and types of offering and resourcing, emerge often due to macro factors (legislation and government policy). It is clear that these changing drivers are encouraging, or in some cases mandating, an enhanced approach to CEE within institutions, and an approach that is responsive to changing market and societal expectations, that consequently requires a balance between organisational agility and sustaining quality and building on central services.

This initial comparison has highlighted a number of key areas for further research and discussion: 1) what are models to resource CEE offerings, and how can an institution choose the most appropriate option? 2) what are the best practices and models around co-creation of CEE offerings? 3) developing a conceptual framework around developing and implementing a CEE strategy; 4) developing a taxonomy for CEE (as had to be partially done for this research to allow consistency in comparison); 5) What CEE offerings should institutions create for their own staff (to meet changing needs of their profession)? 6) expand this initial exploratory research to survey a wider range of institutions to understand practices, drivers and policies to enable CEE; and 7) What is the role of fixed courses/programmes compared to collecting micro credentials, and how are the micro credentials evaluated (for instance given EQF level)?

ABSTRACT

Teaching and learning have always been at the heart of the missions of universities. The growing interest nowadays to pay attention to the quality of higher education teaching results in initiatives such as the establishment of Teaching and Learning Centres (TLCs). The Academy for Learning and Teaching (ALT) at Eindhoven University of Technology (TU/e) has recently been created, and it is still under construction, with the purpose of promoting quality of teaching through engaging staff in interaction and in learning lessons from evidence-based educational practices and innovation in engineering education. Furthermore, ALT supports the professional development of faculty teaching staff through Learning Communities (LCs) as informal learning mechanisms that stimulate knowledge sharing about engineering education experiences across departments (and universities). LCs facilitate interaction with peers, discussions on educational practices, working in

[1] *S.M. Gómez Puente*
s.m.gomez.puente@tue.nl

teams, and exposing academic and education support staff to have access to state-of-the-art research and information on educational issues. LCs are organized by themes, such as Digitalization, that cover topics relevant to innovative practices, e.g., Learning Analytics, Artificial Intelligence in education or Digital Assessment. The purpose of this study is to present the ALT model as a knowledge centre in engineering education that stimulates the advancement of quality teaching. Specifically, we analyze successful factors to constitute Learning Communities, as well as, the motivation of the teaching staff to participate in the LC associated to the TU/e ALT. ALT may serve as an inspiring model for other engineering and technical higher education institutions and universities wishing to promote professional development of teachers.

1 INTRODUCTION

The establishment of Teaching and Learning Centres (TLCs) has arisen in recent years worldwide with the purpose of encouraging better quality of education and teaching, but also to support research in education and innovations (Marbach-Ad et al., 2015). TLCs play an important role in the professional development of faculty, academic teaching staff and educational officers in higher education institutions (Gosling and O'Connor, 2006; Atkins et al., 2017). Research on the value of TLCs points out the benefits to help shaping the professional and academic cultures in addition to instructional practices in the universities (Behling, & Linder, 2017).

Literature on TLCs shows the relevance of setting up linkages and create synergies with institutions' wider communities as well as colleagues at other higher education organizations or TLCs. These linkages make sustainable the purpose of the TLCs, to foster transfer of knowledge and innovations and to promote exchange of activities that can enhance quality of education and teaching.

The outreach capacity of the TLCs aims at targeting not only the primary process of faculty, but also educational staff within a single organization. The functions of the TLCs vary in services and structure being the professional development of teachers; the support to carry out innovations (e.g., the design and implementation of teaching practices); and research in education, the most common activities (Marbach-Ad, et al., 2015).

At the heart of its mission TU/e aims to excel in quality of education and teaching. The three pillars of ALT are the LC as an informal platform for learning, research in innovations in education and the professional development of teachers. In the context of TU/e, innovations within the framework of ALT are meant to support learning from experiments in education, e.g. improving feedback as learning, activating students in large groups, use of technology in education to monitor students' learning, etc. The aim is to research innovations in education to provide evidences and create a culture of bottom-up to quality teaching. Therefore, the establishment of the Academy for Teaching and Learning (ALT) has a crucial role in raising the profile of the university to become an international renowned institution in educational innovation. In establishing ALT, it became important to investigate the factors that constitute an effective knowledge centre, such as:

1. RQ1: What are the successful factors that constitute the organization of Learning Communities (LC)?

2. RQ2: How to encourage teaching staff to actively participate in the Learning Communities?

In the coming sections, the theoretical considerations that frame the construction of ALT are presented. In addition, the methodology and approach to construct ALT is explained. Furthermore, results of the literature review and the participatory consultation are discussed that have given form to ALT. Finally, some reflections/considerations for further establishment of the LC are shared that contribute to further professionalization of the teachers.

2 THEORETICAL CONSIDERATIONS

‘Communities of practice’, ‘learning communities’, ‘collaborative collegial groups’, or ‘networks of professionals’, are oftentimes terms that refer to similar ‘learning structures,’ made up of groups of individuals who share common interests, dilemma’s in educational practices or have a similar goals to improve their practice by interacting regularly with others and engaging in a process of collaborative learning (Wenger, 2006; Wenger, McDermott, and Snyder, 2002).

Theories on education such as situated and contextual learning (Lave and Wenger, 1991), refer to that context and learning should be embedded in a particular social and physical environment. Research shows that involving individuals to share common interests to bring about outcomes, contribute to develop an identity within a community and commitment among disciplinary or interdisciplinary groups. (Handley, Sturdy, Fincham, and Clark, 2006). Research reports about successful experiences of community activities by engaging teachers in problem solving, seeking experience, reusing assets, discussing developments, working together in creating a new curriculum or interdisciplinary courses, and mapping knowledge (Wenger, 2006).

Furthermore, research on the effectiveness of learning communities in promoting advancement of faculty members’ development and in supporting innovation abounds in the literature (Cox, 2001). Harwood et al. (2005) describes the positive experience of faculty members engaged in community seminars to examine their pedagogical practices, as a vehicle to support personal and professional growth as researchers and teachers. Essentially, critical reflection of professionals about what works or does not work are also interesting LCs activities.

Grounded on these theoretical insights, we investigated the characteristics of the learning communities that can lead to a successful implementation. Moreover, we also looked into a model that can stimulate an active participation of the teaching staff in learning communities.

3 METHODOLOGY

The methodology for this study is designed to respond to the research questions (RQs). The methodology consisted of a two-fold approach: (1) Literature review; and, (2) Multi-stakeholders’ consultation.

To answer the RQ (1) *What are the successful factors that constitute the organization of Learning Communities?*, a systematic literature review was conducted. In total 15 journal articles were reviewed. In this study, we only mention the insights of the articles that meet the ALT goals, specifically the focus on LCs. The literature review process followed a systematic approach (Papaioannou, Sutton, and Booth, 2016) of:

- Making a preliminary selection of scientific journals in the field of education, collaborative learning in higher education; professional development; etc.;
- State-of-the-art selection of manuscripts on research on educational practices of learning communities was made within the range of years between 2000 and 2020.
- Search for manuscripts included a classification of words 'communities of practice'; 'learning networks'; 'professional groups in higher education'; 'communities of practices'; 'collaborative learning'; and alike.

To investigate the RQ (2) *How to encourage teaching staff to actively participate in the Learning Communities?,* a stakeholder approach was used consisting of interviews with CTLs, brainstorming sessions and discussions to converge into a model suitable for the context of the TU/e.

3.1 Participants

As a first step to address RQ2, interviews and discussions with staff in national and international CTLs in Europe, Australia and United States of America took place in order to learn from their experiences. Secondly, a Think Tank was organized to brainstorm about the teachers' needs, topics and forms to organize learning communities. Participants were selected by its relevant role in innovations throughout the university. Finally, a consultation and advisory working group was established to converge into a model that may motivate the university teaching staff to actively participate, and eventually, lead a learning community. Table 1 shows the activities and participants involved in this stage.

Table 1. Participants of this study

Participants	Activity
National and international CTLs	Interviews
Think Tank: Program Directors, teachers and education support N=6	Brainstorming about needs, topics and form for LC
Consultation and advisory group (university education management board and ALT management team) N=5	Participatory design of the ALT model

4 RESULTS

4.1 Findings from literature review RQ (1) What are the successful factors that constitute the organization of Learning Communities?

Literature on learning communities in higher education shows the benefits of teachers working in teams, discussing educational practices and engaging in an ongoing cycle of questions that promote deep team learning. Research also points out the successful factors of disseminating innovation results, stimulating interaction and learning from colleagues, as an informal way to contribute to the professional development of academic teaching staff (Sims & Fletcher-Wood. 2021).

Furthermore, engaging teachers in collegial interaction to learn from peers, promoting team teaching activities, supporting co-creation activities and stimulating knowledge sharing in a community are strategies that foster change of culture in an organization and promote institutional-level innovation (Atkins et al., 2017).

Collaboration, sharing knowledge and peer interaction are intrinsic parts of the day-to-day practices of scientific staff and researchers. This way of working nurtures the systemic processes pertaining to a culture of excellence in quality of teaching in universities. Key characteristics from research on factors contributing to successful Learning Communities (LC) refers to (DuFour, 2005; Lutrick & Szabo, 2012):

- **Ownership** of newly acquired knowledge as a sense of empowerment attained as a result of leading a community, organizing meetings, conducting own research projects, etc.
- **Autonomy:** opportunity to select own topics for discussion.
- **Relevance:** topics for discussion are linked to teachers' needs, are relevant for their tasks and aligned to university or departmental strategic vision on education;
- **In-depth:** the value of studying a topic in more depth;
- **Inspiring leadership:** discussions with university/faculty members, being knowledgeable, experience in education and students' learning, acting as a facilitator, etc.
- **Collaboration:** building communities around specific themes is a powerful informal learning mechanism to stimulate collaborative learning among academics as well as to disseminate research. Also, it provides good opportunity to meet on a regular basis with other educators, including their colleagues and the university faculty; interaction; sharing knowledge, etc.
- **Assistance:** to organize and setting up regular meeting times and by keeping the groups focused and moving along.

4.2 Findings from consultation with advisory working group RQ (2) *How to encourage teaching staff to actively participate in the Learning Communities?*

Interviews with national and international CTLs revealed trends in establishing learning communities considering fellows, teaching staff, as an important mechanism to empower academics, but also to foster to professional development. In addition, the construction of these learning niches with a bottom-up approach contributes to a sustainable form to connect people and create networks of knowledge sharing across the university and outside.

Following the findings on successful factors in the construction of CTLs, the ALT model at TU/e, focuses on creating a bottom-up niche, the so-called Learning Communities, for academic as well as for the university educational support staff as a whole, to meet informally, learn and talk about education, the challenges in teaching and learning, in addition to the current developments in innovation in engineering education (See Figure 1).

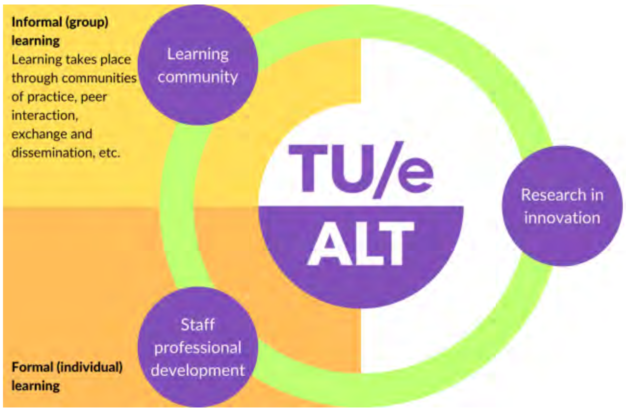

Figure 1. Overview LC informal learning structure.

In the ALT model, a role of fellow is included. Fellows are teaching staff motivated to deepen knowledge in specific educational topics and enhance professional development through educational innovations. Moreover, the approach of selecting fellows, to lead the LCs, follows the rationale to empower teaching staff to develop their vision on education and boost their professional development.. The task of the fellows is to create linkages with departmental academic colleagues, and possibly, across the departments. Fellows lead a thematic LCs and prepare an annual agenda for activities (e.g. get together to solve educational dilemmas, organize seminars, discussions, workshops, webinars with experts/guests from national and international organizations on relevant topics, etc.) and create linkages with national and international LCs. The expected time spent by fellows in ALT activities is at least half a day per week.

ALT learning communities are an interesting opportunity to connect and engage teaching and education staff. Therefore, to realize informal learning in the LC as visualized in the previous figure, the following activities are envisioned (but not limited to) (See Figure 2):

(1) Stimulate consultation, peer interaction and promotes dialogue;
(2) Promote knowledge and experience sharing, information;
(3) Provide mentoring and coaching to (re-)design innovations and put in practices new ideas;
(4) Present research and support in innovations, e.g., how to write an innovation proposal, or how to carry out research on innovation in courses, etc.
(5) Support dissemination of innovations and experiments;
(6) Motivate reflection on vision on education.

Figure 2. LCs opportunities: connecting and stimulating teachers' knowledge sharing

5 CONCLUSIONS

The establishment of ALT is an exciting and challenging undertaking. The benefits of participating in ALT Learning Communities lies in the possibilities to engage in university-wide innovations in education and learn from colleagues from other departments. Opportunities to broaden the scope of practice in innovations in engineering education and to reflect upon results from experiments, lessons learned and research are provided in the round tables, discussions on dilemmas in classroom practices and alike, organized within the LC events.

Moreover, the fact that teachers and education staff from different departments will attend the LC will facilitate the transfer of knowledge and information to own departments contributing, therefore, to stimulate the cross-pollination effect across disciplines, staff and beyond the borders of the departments.

Ultimately, Learning Communities can contribute to promote the quality culture of the organization and nurture the culture of change by participating in enriching and updating the university vision on education with new insights. Leading a Learning Community can also create an impact on teachers' professionalization in education.

Conference Key Areas: Curriculum Development, Fostering Engineering Education Research

Keywords: Bachelor's thesis, seminar work, thesis supervision

ABSTRACT

A Bachelor's thesis is typically an individually written literature review on a scientifically relevant topic. Additionally, some theses also describe empirical work or report an experiment. Firstly, we introduce how Bachelor's theses are supervised in a joint thesis seminar for Computer Sciences and Information Technology at our university. The thesis seminar is organized three times a year. It consists of six small group meetings led by a supervisor and contains compulsory pre- and post-assignments and active peer discussions. In 2022, there were in total of 187 students participating in the spring, summer and autumn seminars. Secondly, we give an overview of the 98 completed theses. We classify the theses using ACM's Computing Classification System and analyze keywords, the number of references and some other bibliometrics to learn about the students and the potential effects of their different study orientations. We also analyze 14 theses that reported practical work, like the implementation of an algorithm or using existing software tools. The main result of our work is to give a research-based view on the supervision of Bachelor's theses, the organisation of the thesis seminar, and the bibliometrics of the completed thesis.

*Corresponding author

1 INTRODUCTION

In 2019 the two universities in Tampere (University of Tampere, and Tampere University of Technology) were merged into Tampere University (Tampere University 2018). The new multidisciplinary university is the second largest in Finland with almost 20,000 students in bachelor's degree and master's degree study programs. The universities had degrees in Computer Science (CS) and Information Technology (IT) with good records of graduates throughout the years. While the separation between the academic fields is profound, and the graduates will still get their diplomas in BSc or BSc in Technology, it is most visible in other than the major field of study, since the degree programmes share most of the software-related studies. Since the merger, teaching has also been harmonised between different cultural and skill backgrounds to cope with the ever-increasing numbers of students, the demands of the pandemic and the pedagogical changes that all these have brought.

In this paper, we focus on Bachelor's theses and the thesis seminar where they are supervised. The thesis is one of the final tasks for the student before graduation, usually in the third or fourth year of study. It would be in the interests of the faculty to get more graduates yearly since part of the funding is based on the number of Bachelor's and Master's degree diplomas awarded, and the funding model emphasizes on-time graduates - those who complete their degree in three academic years.

The aim of our research is to look into the joint thesis seminar to see how well it serves the degree and learning goals of the CS and IT degree programmes. Our research question is:

1. What kind of theses are completed, and do they indicate differences between CS and IT students?

Our analysis is based on the accepted theses available in the public thesis database of the university as well as the enrollment statistics for the 2022 calendar year.

The rest of the paper is structured as follows. In Section 2 we describe the background of the Bachelor's thesis in the computing curricula. In Section 3 we focus on our implementation, its learning outcomes and seminar structure. Section 4 shows the results of our analysis of seminars in 2022. The results are discussed in Section 5 which concludes the paper.

2 Bachelor's thesis in computing curricula

A Bachelor's degree includes either a thesis or a large-scale final project (e.g., a capstone project). In Europe, a thesis seems to be common at universities, and final projects occur more often at universities of applied sciences but this is not a rule. The length of a European Bachelor's degree is three or four years as stated in the Bologna Declaration (European Higher Education Area 1999). In the USA, a capstone project is common instead of a thesis seminar (Blumenthal 2022), especially in the context of industry projects (ACM 2020). The U.S. Bachelor's programmes are mostly four years.

Bachelor's theses are also closely tied to the teaching of research methods, as a properly written thesis contains a literature review that ties the work into existing knowledge in the research area. Koppelman et al. (Koppelman, Dijk, and Hoeven 2011) reported in their case study findings from an undergraduate research course. One of their results was that students feel better prepared to conduct research in graduate programs after the research course. Holz et al. (Holz et al. 2006) point out the large variety of research methods in computing and discuss how they should be taught to students. In our study programs research methods are discussed in the MSc level. However, the literature review approach naturally involves getting familiar with the research methods applied in the literature of one's study field.

2.1 Bachelor's theses in higher education programmes

In Finnish BSc degree programmes, a thesis of a minimum of six and a maximum of ten credits is required by the legislation (Finlex 794/2004 2004). The credits follow the European credit system ECTS (European Commission 2015) where one credit is $26\frac{2}{3}$ hours of student work. Together the seminar and the thesis bring 10 ECTS. The full academic year is 60 credits, and the Bachelor's degree 180 credits in the relevant areas of this paper.

2.2 Bachelor's thesis guidelines

The Bologna process does not specify anything about the Bachelor thesis. Likewise, a thesis is not mentioned in the ACM Computing Curricula 2020 (ACM 2020) though it encompasses BSc programmes in Computer Engineering, Computer Science, Cybersecurity, Information Systems, Information Technology, and Software Engineering. Some earlier computing curricula recommendations by the ACM require a final project, but only the Chinese version of the information technology curriculum includes a graduation thesis (ACM 2017). In computer engineering, one example curriculum mentions a final individual project that includes a thesis (ACM 2016), and in computer science, one example curriculum recommends project courses with a note that a "Reading, Research, or Thesis course" is not enough (ACM 2013).

The only example curriculum containing a Bachelor thesis is the Chinese four-year version of the information technology curricula. It describes the contents of the thesis as follows: "Students do literature translation, literature survey, opening report, system design and development, thesis writing and defending; students acquire scientific research ability, system design and development ability, develop a basis for future work." (ACM 2017) In this respect, the ACM reflects the practices in the USA. However, even if the theses are common in Europe, the Bologna process does not mention a Bachelor-level thesis.

Universities have published local guidelines for bachelor theses, which may be subject-specific or aimed at the whole university. The study guide of Tampere University falls into the latter category. The objectives of the thesis are described as follows.

> With a bachelor's thesis, students demonstrate their ability to apply their acquired knowledge and skills, engage in scientific or artistic thinking and activities and communicate effectively, both orally and in writing, in their mother tongue. Students typically attend a bachelor's thesis seminar while working on their bachelor's thesis. (Tampere University 2019)

3 BSc thesis seminar in computer sciences and information technology

Our paper discusses theses written as a part of a three-year Bachelor's programme at Tampere University. The BSc theses in Computer Sciences and Information Technology are completed by taking a semester-long thesis seminar course. The seminar is arranged three times a year - Autumn, Spring and Summer.

3.1 Learning outcomes

In the seminar, there are two main learning outcomes that are common to students of both degree programs.

1. Learn how to do a small research work with the structure of a common research paper.
2. Learn to write scientific text.

However, the learning outcomes for the Bachelor's thesis in Computer Sciences and in Information Technology are verbalized separately for each in the current curriculum. This is due to the histories of two separate universities, and will undergo further unification for the next curriculum period 2024-2027. Still, when coded together, the core learning outcomes are common for the two degrees both aiming for a completed BSc thesis required in the degree. Together, they include the following. After completing their thesis:

- The student has practised writing a thesis. They know how to design and write a thesis and how to take the academic audience into account.
- The student has experience in searching for and reading scientific and technical papers and writing their results comprehensively. They are able to systematically search for information and recognize the sources relevant to their field. The student knows how to evaluate and utilize sources of information in their thesis and is able to exclude sources not relevant to their work.
- The student has practised interaction with other professionals and knows how to give and receive scientific critique. Their comments are useful and constructive. The student is able to evaluate comments and handle them appropriately.
- The students know how to analyse the key elements of a research problem and their relationships. They understand the nature of the scientific writing process and can apply it in practice.

In the learning outcomes, differences can be identified in the target audience of the thesis. IT highlights the technical engineering audience while CS targets a more holistic professional audience. CS emphasizes the ability to form and defend independent views regarding a research problem while IT takes a more practice-driven approach of verbalizing the learning outcome through the ability to present the student's work and to act as an opponent. CS mentions the ability to address ethical concerns explicitly. IT addresses the ability to take the reader's needs into account.

Between the two degree programs, the main differences in requirements can still be associated with academic writing studies. Whereas students in Information Technology complete an "Academic Writing" module integrated into the seminar, the students in Computer Science have a separate scientific writing course with a scope of 2 ECTS. The reason for such imbalance lies in the differences of the study fields. As the engineering students have natural sciences (mathematics, physics, chemistry) as required studies, their study program is tightly packed into 180 ECTS to match three years of study, and for them, the integration of writing counselling to the seminar itself does not produce credits.

As a form of thesis, a literature review is recommended but constructive research is allowed. In all cases, a thesis is based on a literature review on the topic. Planning and carrying out empirical or constructive research often takes long, thus causing more student workload than expected for the seminar, and possibly lengthening the process of graduation. All students enrol in empirical group projects in their studies to gain practical experience, and in our curricula, these projects are separate from the thesis seminar.

The minimum length of the thesis is 10 pages and it should not exceed 25 pages. It can be written in Finnish or English.

3.2 Thesis evaluation

The theses are evaluated with a five-level grading scale: 1 (sufficient), 2 (satisfactory), 3 (good), 4 (very good) and 5 (excellent). In principle, the thesis might also receive a failed grade, but the supervision process prevents this as the supervisor does not allow the student to make an official submission before the thesis reaches an acceptable level. After the student has submitted the thesis for assessment, the supervisor has 21 days to evaluate the thesis by writing a statement. The statement is then approved by the responsible teacher before it is forwarded to the administration.

The evaluation is based on nine criteria: i) Topic, objectives and thesis title; incl. research question. ii) Structure; structuring the topic and logic of the structure. iii) References; quality, quantity and usefulness, citation practices. iv) Conclusions, achievement of goals and criticality. v) Language, text fluency and appearance (incl. figures and tables). vi) Self-initiative and consideration of feedback. vii) Seminar work activity. viii) Presenting the work and being an opponent in the final seminar meeting. iv) Completing the thesis on schedule. The final grade is not necessarily the average of the criteria, the emphasis depends on the topic, content, and other relevant factors.

3.3 Seminar structure and supervision

Arranging the seminars requires lots of coordination work by a team of responsible teachers who handle general arrangements before, during and after the seminar. Each seminar instance needs to have both students that enrol with initial ideas of their interests and a preliminary topic for the thesis, and supervisors that are experts in the topics chosen by the students. In addition to the content experts, the students also meet with information search experts of our University Library, and Academic Language teachers.

At the start of the seminar, the enrolled students are divided into small groups of 4 to 8 members based on their initial topics. Every small group is led by an experienced teacher or a professor. The groups follow the meeting agendas described in Table 1. The meetings are held two, three or four weeks apart, depending on the phase of the seminar. We have Moodle (Moodle LMS 2023) as our learning management system, hosting both timed discussion forums for the small groups as well as links to shared lecture videos and practical advice on the required tasks.

Table 1: Seminar structure and group meetings

Before the seminar	Enroll, indicate individual interest areas and initial topic.
Group meeting 1	Meet the supervisor and group members. General ideation.
Group meeting 2	Make first mind map, write motivational paragraphs on the topic.
Group meeting 3	Information search with keywords to find articles, make a concept map.
Group meeting 4	Combine the parts into a thesis outline, indicate missing parts.
Group meeting 5	Write missing parts into an almost complete thesis document.
Group meeting 6	Prepare a presentation. Give detailed feedback as an opponent.
After the seminar	Finalize the thesis and submit it.

The full duration of the seminar is roughly four months, and the students are expected to finish their theses within one to six months after the end of the seminar. All theses are checked against plagiarism and stored in the document repository of our university (Tampere University 2023).

The seminar is started by more students than finish it (Table 2). Similarly, the number of completed theses is lower than the number of completed seminars. Partly the low completion rate is due to the administrative delay of several weeks between the submission of the thesis and it becoming available in the document repository. This is why we extended our data collection until the end of January, as indicated in (Table 2).

4 BSc theses in computer sciences and information technology

Our analysis is based on the 98 accepted theses acquired from Trepo (Tampere University 2023). 90 theses were written in Finnish, and 8 theses in English. Most of the theses, 93,

Table 2: Seminars, participants, and completed theses 1.1.2022-31.1.2023.

Start time	Enrolled	Completed seminar	Completed thesis
Spring 2022 seminar	89	65	57
Summer 2022 seminar	32	21	14
Autumn 2022 seminar	66	44	27
Total	187	130	98

are publicly available online, and 5 theses have only abstracts and keywords online. These five theses can be read at the thesis point in the university library.

4.1 Keyword and topic analysis

We categorized the thesis topics using ACM's Computing Classification System (ACM 2012). The ACM CCS is first briefly explained to the students as they start their information search for thesis topics. We have found it a good starting point in search for up-to-date references. The categorization of our thesis sample (98 theses) is shown in Table 3.

Table 3: Theses categorization using ACM's Computing Classification System.

CCS category	IT students	CS students	All
Applied computing	3 (5.2%)	4 (10.0%)	7 (7.1%)
Computing methodologies	4 (6.9%)	5 (12.5%)	9 (9.2%)
Computer systems organisation	5 (8.6%)	0 (0.0%)	5 (5.1%)
Hardware	2 (3.4%)	0 (0.0%)	2 (2.0%)
Human-centered computing	5 (8.6%)	12 (30.0%)	17 (17.3%)
Information systems	10 (17.2%)	2 (5.0%)	12 (12.2%)
Mathematics of computing	0 (0.0%)	0 (0.0%)	0 (0.0%)
Networks	0 (0.0%)	0 (0.0%)	0 (0.0%)
Security and privacy	6 (10.3%)	5 (12.5%)	11 (11.2%)
Social and professional topics	4 (6.9%)	3 (7.5%)	7 (7.1%)
Software and its engineering	14 (24.1%)	7 (17.5%)	21 (21.4%)
Theory of computation	5 (8.6%)	2 (5.0%)	7 (7.1%)
Total	58 (59.2%)	40 (40.8%)	98 (100%)

Mathematics of computing students complete their thesis in a separate seminar with students of mathematics and statistical data analytics. Similarly, students of Networks participate in the BSc thesis seminar in Electrical Engineering (EE). This is due to Networks as a major being common to IT and EE, and as the students are grouped based on their initial topics, it makes sense to keep the Networks students together. Hence these two categories do not have students in our analysis.

The distribution of IT and CS students' thesis topics is in line with the profiles of the degrees with IT being geared toward software engineering, information and computer systems while CS has more of an emphasis on human-technology interaction. Societal aspects and information security are equally present in both. Each student chose up to six keywords to describe their thesis work, and we combined those keywords into loose semantic clusters that are presented in (Table 4) according to their size.

Specific development techniques and tools (such as React, Django, Java, Javascript, C++, Python, ...) often appeared in the keyword lists but were left out of this analysis.

Table 4: Clusters of most common keywords in the theses.

	IT students	CS students	All
1. software engineering, agile, projects	15	7	22
2. machine learning, neural networks	9	6	15
3. algorithms, computation	6	9	15
4. information security, cybercrime	3	11	14
5. programming, web, mobile	4	7	11
6. accessibility	2	9	11
7. data science, data bases	5	5	10
8. usability, user experience	3	6	9
9. social media	3	3	6
10. recommender systems	3	3	6

4.2 Thesis bibliometrics

Thesis bibliometrics for a number of pages, words and references are listed in Table 5. The minimum page length required is 10 and the minimum word count for a thesis to be acceptable is 3000 words. The thesis should have a minimum of 10 references with 15 as the recommended average. The average number of pages in the theses was 18.48. The shortest thesis was 11 pages and the longest was 30 pages. An average CS thesis was 17.6 pages and an average IT thesis was 19.09 pages long. IT students seem to write longer theses as the shortest CS thesis was 11 pages and IT 12 pages, and the longest CS thesis was 24 pages while the longest IT thesis was 30 pages. However, the thesis template in IT renders more pages and thus the number of words gives a better comparison point.

Table 5: Average number of pages, words and references of CS and IT theses.

	Pages (min/ave/max)	Words (min/ave/max)	Ref. (min/ave/max)
CS students	11 / 17.60 / 24	3215 / 4986.74 / 7920	12 / 19.45 / 33
IT students	12 / 19.09 / 30	3105 / 5099.04 / 8303	10 / 18.97 / 44
All	11 / 18.48 / 30	3105 / 5053.15 / 8303	10 / 19.16 / 44

The shortest thesis was 3105 words (IT) and the longest, also in IT, 8303 words. The longest CS thesis was 7920 words. On average the theses were 5053.15 words long. The IT average, 5099.04, was a bit higher than the CS average of 4986.74. However, the differences are not significant.

The average number of references was 19.16 (19.45 in CS, 18.97 in IT). The smallest number of references was in an IT thesis, 10. In CS, the lowest amount of references used was 12. Similarly, the largest number of references was found in an IT thesis, 44 with 33 references respectively in CS. The students are expected to discuss the scientific quality of the studies they write about in the thesis. Our reference counts do not take into account the quality or the publication forums of the references. That kind of analysis might indicate more differences between the student cohorts, the IT students being more oriented towards practice.

4.3 Theses with practical experiments

All the analyzed theses contain a literature review on the topic. There were 14 theses that reported a practical study. These theses can be classified into three main categories (the number of theses in the category is given in the parenthesis):

A) Implementing an algorithm or designing a method or model, or designing a challenging and useful example. (7)

B) Applying existing tools to evaluate something. (3)

C) Collecting data with different methods from different sources and then comparing the collected data. (4)

The seven theses in category A described often an implementation of a commonly known algorithm, like the A* search algorithm or a method to generate random numbers. In most cases, they also contained a small-scale evaluation. Some students published their source codes in a public code repository.

Theses in category B (3 theses) reported applying some existing software tools to experiment, collect and compare data. For example, a student studied accessibility reports generated with WAVE on some web e-commerce sites.

Then there were 4 theses (category C) that reported a comparison based on data that was collected from the literature or from other sources, like websites. For example, in one thesis data was collected using a questionnaire form, and in another thesis, data was collected from GitHub, Stack Overflow and LinkedIn.

5 DISCUSSION AND CONCLUSION

To answer our research question, we did not find significant differences between the CS and IT students' theses.

Minimum requirements have an impact on the overall quality of the thesis. Mostly the students wrote theses exceeding the minimum requirements and the average thesis was along the lines of the recommended, not the minimum. While there are differences in the topics and research methods, having common quality guidelines can be viewed as beneficial.

We sought for causes behind the large number of dropouts (see Table 2). A closer look into the dropout statistics reveals some facts. In 2022, altogether 7 students enrolled twice or even three times in the seminar. From them, only one student has finished the thesis after the second seminar by the time of writing. One reason for this may be that many students in the Computer Science and Computing fields are more qualified in writing Python, C++ or similar code segments than in natural languages. For them, writing the thesis seems difficult and beyond the skills of the student. Similar results pointing out the importance of beliefs of self-efficacy are brought up e.g. in (Blankenstein et al. 2019).

A second cause for discontinuing the seminar is beyond the scope of the seminar itself. Despite our efforts on the seminar arrangements, the thesis is often postponed as far as possible. After graduation most students continue in their Master's degree program and there is no clear cutoff point between the programs. To complicate the matter, Finnish students do not pay study fees in higher education, and they do not see graduation as high on their priority list. Many of them carry out outside jobs to support living or work in an internship to gain experience in the study field, leaving less time to focus on their studies. The national BSc students' survey findings (Education Statistics Finland 2023) for 2022 found that the top three main causes of delays in studies were the lack of motivation to study, health-related reasons and working. The lack of motivation was the leading cause and was on the rise from the previous year. While not directly in the hands of the thesis seminar alone, these aspects are important to take into account and address when planning the seminar.

To wrap up, finding a suitable topic and the motivation to spend time on it to write a thesis requires resilience from the students. A comforting fact is that while thesis writing may take time over the intended time frame, most students eventually get their thesis completed, and the seminars enable effective focusing on thesis writing.

ABSTRACT

Ethical concerns in the digital domain are growing with the extremely fast evolution of technology and the increasing scale at which software is deployed, potentially affecting our societies globally. It is crucial that engineers evaluate more systematically the impacts their solutions can have on individuals, groups, societies and the environment. Ethical risk analysis is one of the approaches that can help

reduce “ethical debt”, the unpaid cost generated by ethically problematic technical solutions. However, previous research has identified that novices struggle with the identification of risks and their mitigation. Our contribution is a visual tool, the Digital Ethics Canvas, specifically designed to help engineers scan digital solutions for a range of ethical risks with six “lenses”: beneficence, non-maleficence, privacy, fairness, sustainability and empowerment. In this paper, we present the literature background behind the design of this tool. We also report on preliminary evaluations of the canvas with novices (N=26) and experts (N=16) showing that the tool is perceived as practical and useful, with positive utility judgements from participants.

1 INTRODUCTION

The ethical issues with software released to the public, especially Artificial Intelligence (AI)-based software, are so widespread that some researchers have coined the term “ethical debt” (Petrozzino 2021; Fiesler 2020). Paralleling the notion of technical debt (Knesek 2016), ethical debt represents the unpaid cost generated by ethically problematic software and borne by individuals, communities, and society in general. However, while technical debt is typically the result of deliberate choices guided by specific imperatives (e.g. time to market), ethical debt mostly arises from unidentified ethical risks (Fiesler 2020; Petrozzino 2021).

Engineering education has a responsibility to address this situation. Isaac et al. (2022) have shown that novice software engineers tend to neglect ethical concerns in their design. Griffin et al. (2023) report that experienced software engineers do not necessarily identify that technical decisions they routinely make in their professional activities have ethical implications. Whether they will be users, integrators, designers or developers, the engineers we train need to develop strategies for a) systematically identifying and assessing ethical risks associated with digital solutions[2] and b) identifying possible mitigation options to the ethical issues they identify.

In this paper, we present a visual guide called the “Digital Ethics Canvas” designed to help engineering students work through ethical risks specifically related to digital solutions. We first review previous work before discussing the foundations for the ethical framework underlying our canvas and present preliminary evaluation results.

2 BACKGROUND

A “canvas” is a visual tool designed to guide people through the process of using a methodology or framework. Canvases are increasingly used in engineering education (Tranquillo, Kline, and Hixson 2016), for instance to support specific engineering tasks (Ruf and Back 2015) or to support education activities in an engineering context (Ammersdörfer et al. 2022). The canvas that we propose has two specificities: a) it focuses on the analysis of the risks generated by a digital solution under design, development or use and b) it is built on six ethical “lenses” that guide risk assessment and mitigation. In the following, we position our approach compared to existing work on these two aspects.

2.1 Risk analysis

Risk analysis is an important aspect of engineering work and encompasses two types of risks: risks to the product/service being engineered (i.e. hazards that could

[2] Throughout this paper, we use the term “digital solution” to refer to technical systems that involve software and the infrastructure needed to run it. We chose this term to encompass a wide range of software-related technologies, such as IA, Internet of Things, Big Data, social networks or web apps.

make the engineering project fail) and risks generated by that product/service (i.e. adverse effects that the product/service could have on individuals, groups, societies and the environment). While the former are important from a project and business management point of view, the latter are at the core of responsible engineering and the focus of our work. Our goal is to develop the ability of engineers to identify the specific risks generated by digital solutions to others, society and the environment (also called ethical sensitivity).

Vallor (2018) proposes “ethical risk sweeping” as a tool for avoiding “ethical negligence”. She argues that ethical risks analysis should be a standard engineering protocol in the same way as cybersecurity penetration testing, and repeated at all phases in the engineering process, from the initial product proposal to the quality assurance stage. However, her proposal does not make explicit how engineers can analyze these ethical risks in practice.

Carlson et al. (2018) have studied how students analyze risks in the context of projects involving real-world problem solving. They found that students struggled with three aspects of risk analysis: identifying risks, setting priorities and working on mitigation (Carlson et al. 2018). They have proposed two canvases to support students: a Design Canvas to identify risks in the problem space and an Iteration Plan to prioritize and set mitigation goals. However, they define risk as “the probability that the design project fails to make impact”, which does not include risks generated by the impact the design project will make.

Among other methods frequently used in strategic analysis, the SWOT matrix (Strengths, Weaknesses, Opportunities, Threats) includes a risk analysis component within its “Threats” section (Weihrich 1982). However, its main drawback from our perspective is that it also considers only risks to the project. A similar drawback is found in other risk analysis canvases such as (Borbinha, Nadali, and Proença 2015) or (Kuru and Artan 2020).

Taking a different approach, Reijers et al. do not focus on risks per se but on “how a technology might bring about ethical impacts for different stakeholders” (Reijers et al. 2018). Designed for practitioners who do not necessarily have an ethics background, their “Ethics Canvas” implements a four-phase process, from stakeholder and impact analysis to mitigation design. Two clear strengths of the Ethics Canvas are its focus on risks generated by a product/service and its domain-agnostic approach, which makes it suitable for a wide range of disciplines and applications. On the other hand, it might be difficult for novices to think about certain ethical concerns. For instance, while privacy and fairness issues seem to gain increasing visibility in software engineering, other concerns such as sustainability and environmental impacts seem to be less frequently addressed (Isaac et al. 2022). In the next section, we review different approaches that try to tackle this issue.

2.2 Ethical lenses

Value-oriented methodologies such as Value-Sensitive Design (Friedman, Kahn, and Borning 2002) typically approach the range of ethical concerns by having stakeholders identify explicitly the “human values” that the product/service should align with. Value-based approaches are getting a lot of traction in engineering and are sometimes even referred to as “ethics by design” approaches (Spiekermann and Winkler 2020). Focusing on values can be seen both as a strength and a weakness: on one hand, the contextual nature of values makes these approach flexible and adaptable to a broad range of contexts, but on the other hand, appropriately defining the values at stake and frame them so that they mean the same thing to all parties

can be challenging (Friedman et al. 2021). The very concept of value has actually been deemed unclear and insufficiently defined (Manders-Huits 2011).
Some authors argue for a more normative approach based on predefined ethical principles (Manders-Huits 2011). Cardia et al. (2017) for instance, propose a canvas based on the four humanitarian principles (humanity, neutrality, impartiality and independence) to assess the use of digital technology for humanitarian action. The four bioethics principles (beneficence, non-maleficence, autonomy, and justice) are often used as an ethical framework for evaluating engineering solutions in healthcare contexts, such as in (Cawthorne and Robbins-van Wynsberghe 2020). By definition, principle-based approaches are possible only when there is an overall agreement on the set of ethical principles to use. This is the case for the humanitarian domain (Council of the EU, European Parliament, and European Commission 2008) and for the medical domain with the largely adopted principles of biomedical ethics (Beauchamp and Childress 1979). As we will discuss in the next section, this is not (yet) the case for the digital domain. In addition, the engineers we train will work in a variety of contexts with varying sets of values (e.g. healthcare, social media). This is why we adopt instead the notion of ethical “lenses” as proposed by Isaac et al. (2022), which represent multiple ethical perspectives for analyzing risks.
The five “lenses” from Isaac et al. (2022) stem from the human-centered design criteria feasibility, desirability and viability (IDEO 2000) that the authors extended with sustainability, privacy and accessibility. Guiding analysis with several criteria is also found in the PEST/PESTLE framework (Political, Economic, Social, Technological / Legal, Environmental). Meant for “scanning” macro-environmental factors in business development (Aguilar 1967), this framework is often used in combination with SWOT. Other authors have instead reinterpreted existing canvases in light of such criteria. For instance, Gillet et al. (2022) propose two reinterpretations of the Value Proposition Canvas (Osterwalder et al. 2014), focused on sustainability and transparency. In contrast to this approach and with the goal to help engineers “scan” risks from multiple ethical perspectives, we propose a single canvas that implements several ethical lenses. In the following section, we discuss the ethical lenses we chose in light of the existing literature on ethics in the digital domain.

2.3 Digital-specific ethical lenses

With the increasing visibility of ethical issues with digital solutions, researchers and practitioners have attempted to clarify adequate ethical guidelines. A significant number of proposals stem from the Big Data and Artificial Intelligence domains. In their “Data, responsibly” proposal, Stoyanovich, Abiteboul, and Miklau (2017) recommend fairness, diversity, transparency, equality and data-protection as the foundations for responsible data science. Ballantyne (2018) later argues that “there is no one-size-fits-all framework for how to ethically manage your data” and suggests seven ethical values for “making informed, explicit, and justifiable trade-offs, rather than following a set of prescribed rules”: social value, harm minimization, control, justice, trustworthiness, transparency and accountability. Howe and Elenberg (2020), take a medical research stance and suggest autonomy, equity and privacy as the ethical concepts most challenged by big data in health. Interestingly, the issue of sustainability and environmental impact is mostly absent from these proposals.
In the domain of AI, Jobin, Ienca and Vayena (2019) analyzed 84 documents in the context of the “ethical AI debate” to identify whether a global consensus was emerging. They identified that 88% of the documents had been published after 2016 and conclude that “No single ethical principle appeared to be common to the entire

corpus of documents, although there is an emerging convergence around the following principles: transparency, justice and fairness, non-maleficence, responsibility, and privacy.”. Loi, Heitz and Christen (2020) extended this work with a focus on the procedures recommended in these AI ethics guidelines and propose a framework with seven principles: beneficence, non-maleficence, autonomy, justice, control, transparency, accountability. Ryan and Stahl (2020) also extended the work from Jobin et al. but with the goal of providing the most comprehensive list of ethical principles as found in 91 guidelines. It is the only contribution we found that included sustainability and environmental impact, reflecting an overall lack of attention to a pressing issue to which digital solutions are actually no stranger (Bender et al. 2021). Other authors take a radically different approach and put forward the human rights framework as a cross-cultural and globally agreed framework for responsible AI (Prabhakaran et al. 2022).

With this short review we want to highlight the current lack of consensus on the ethical principles that should guide a responsible approach to software. It is important to note that this landscape is moving extremely fast and is influenced, of course, by the crucial work done on software and AI regulation worldwide. A flagship of this work is probably the “Artificial Intelligence Act” from the European Commission, which follows a risk-based approach to classify AI-based systems in terms of impacts on safety, security and fundamental rights.

In terms of canvas-based approaches, we found one digital-specific ethics canvas: the Technology Impact Cycle Tool (TICT) (Fontys University 2021). Focused on reflection, it uses questions organized in “scans” of progressive scope with 10 different categories: impact on society, human values, privacy, inclusivity, transparency, bad actors, sustainability, data, stakeholders and futuring. While we found the organization in progressive scopes helpful, we thought that the tool had too many categories and was mixing design process aspects (e.g. stakeholder analysis) with ethical lenses (e.g. privacy, sustainability). We also argue that, while reflection is certainly important in responsible design, an analytical approach of the risks generated by a solution is essential to reducing ethical debt.

3 THE DIGITAL ETHICS CANVAS

As our review highlighted, very few options exist to help engineers identify and mitigate the range of ethical risks generated by a digital solution under design, development or use. Our contribution is a canvas (Figure 1), that helps engineers to scan the risks generated by a solution with six digital-specific ethical lenses: beneficence, non-maleficence, privacy, fairness, sustainability and empowerment. Following an incremental process and taking inspiration from the bioethics principles in particular, we have integrated ethical lenses progressively into our canvas. Our “beneficence” lens is positively oriented, for documenting the expected benefits of the solution. The “non-maleficence” lens is meant to capture safety and security issues, as suggested by Ryan and Stahl (2020). Our “empowerment” lens reflects the autonomy principle but with a larger scope to encompass issues of transparency, explainability, trust and user agency. Our review showed that “justice” and “fairness” are often grouped together (see previous section) but we chose to use “fairness” as a less normative concept which is more frequently used in relation to AI-based solutions. Finally, we added a “privacy” lens to capture risks with regards to the use of data and “sustainability” to include risks related to environmental impacts and labor exploitation. An important factor in our choice was to limit the number of lenses not to overwhelm novices, while being general enough to capture a range of ethical risks. We were also careful not to be too Big Data- or AI-specific and made sure our canvas can be applied to other types of digital solutions. For scaffolding purposes, we included questions in the canvas for the different lenses to help our users surface elements in the digital solution that are likely to give rise to risks, rather than providing them with definitions (see Figure 1).

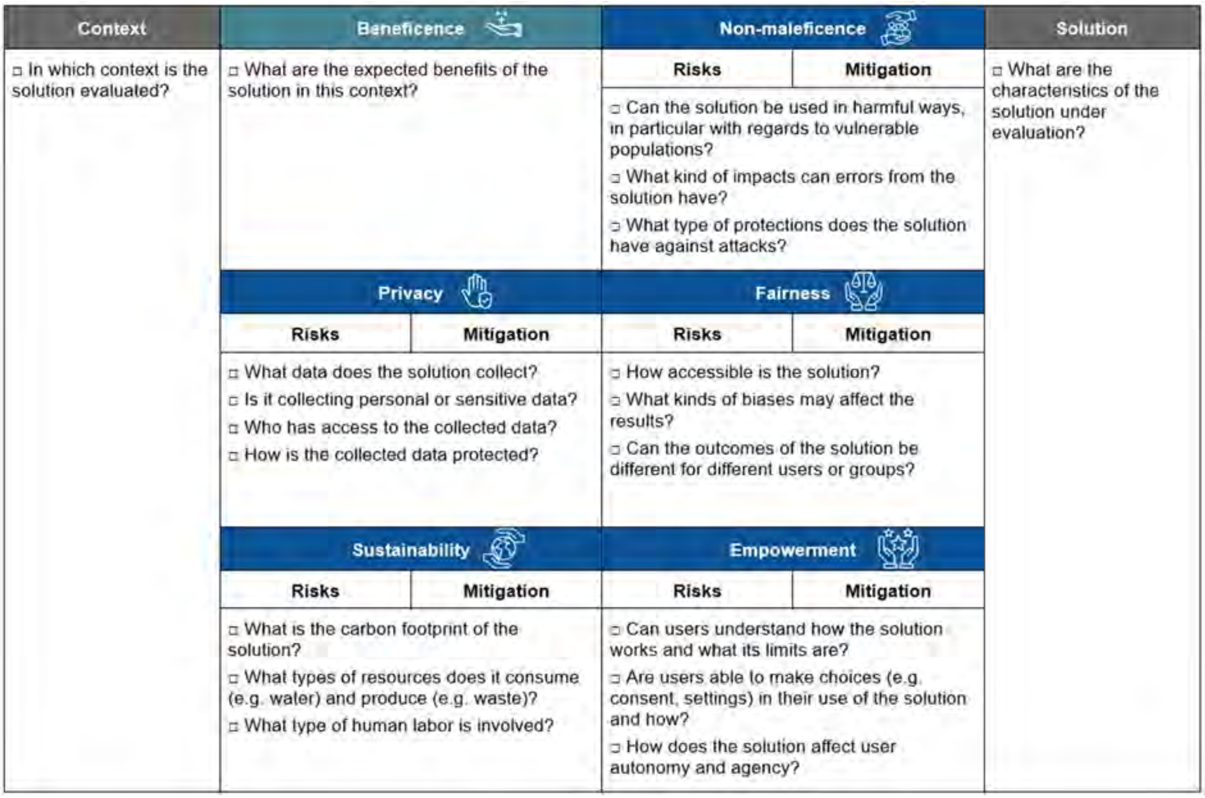

Figure 1: The Digital Ethics Canvas. The left and right columns are used to map out factual information about the digital solution and the context, whereas the central part is used for evaluating the benefits, risks and mitigation options for the solution using our ethical lenses.

With one benefit-oriented lens and five risk-oriented lenses, our canvas supports users in benefit-risk analysis, a methodology which is widely used in public (European Medicines Agency 2018). Benefit-risk analysis is part of a broader family of Multi-Criteria Decision-Making methods (Zionts 1979), typically used in the case of multiple conflicting objectives, as is generally the case with ethical decisions. This type of analysis requires collecting information about the problem space and context, which is why our canvas includes sections to map out factual information about the digital solution and its context of use. For each of the risks, mitigation strategies can be described, as these can weigh in the analysis. Depending on whether the canvas is used at design/development or at use time, mitigation strategies may involve either modifying the technological artifact (e.g., avoid collecting personal data that is not needed to reduce a privacy risk) or changing the usage context (e.g., ask users to provide a nickname rather than their actual name).

4 EVALUATION

4.1 Methods

We have developed our canvas incrementally, testing our ethical lenses and our approach with different types of audiences and applications. In this paper, we report the results of two small-scale evaluations conducted in the spring semester 2023.

We collected the views of novices in a three-hour session dedicated to responsible design as part of a master course on Information Systems Design with 26 students of various backgrounds (15 women, 11 men). We facilitated an interactive presentation of the canvas and its ethical lenses, then students applied the canvas on a case study, followed by a class discussion. The second evaluation was a part of a 90-minute workshop on the ethics of using generative AI for education, for experts in the fields of ethics, engineering, and education. The experts had various backgrounds and levels of seniority (N=16, 11 women, 5 men). We introduced our ethical lenses one after the other with inputs from research on generative AI and time for analyzing the corresponding risks in a given scenario (e.g., a teacher using generative AI to generate deepfakes instead of recorded lectures).
At the end of each session, we asked participants to fill out a survey with both affective reactions and utility judgment measures (Alliger et al. 1997). We captured participants' perceptions about the canvas with the AttrakDiff questionnaire (Hassenzahl, Burmester, and Koller 2003), which has 10 items with pairs of opposite adjectives and a scale from 1 to 7, every other item being reverse-scored. In addition, participants were asked “How would you describe the canvas to your friends?”. The second part of the survey asked participants their perceptions about several aspects of the session on a 4-point likert scale. To assess the perceived utility of the canvas, we asked participants if they thought what they had learned in the session would be useful to them later, if they were likely to apply what they learned in other contexts and if they wanted to have access to the canvas for further use. For novices, learning outcomes were also evaluated in a mid-term exam question the following week.

4.2 Results: perceptions about the canvas

The results of the AttrakDiff items are shown in Table 1. All the adjective pairs are presented with the negative adjective on the left (valued 1) and the positive on the right (valued 7), taking reverse-scoring into account. For each question, we indicate the mean score and standard deviation for both the novices and the experts. The star notation indicates when the mean score is significantly different from neutral (4) as assessed with a single-sample t-test.
The most statistically significant measures indicate that both novices and experts found the canvas ‘good’ (M = 5.92 for novices and M = 6.44 for experts respectively), ‘practical’ (M = 5.35 and M = 6.06) and ‘useful’ (M = 5.84 and M = 6.50). One more measure is statistically significant for the experts suggesting they also found the canvas ‘stylish’ (M = 5.81). All other mean scores are above the neutral value (4 of 7) and a majority higher than 5. These results indicate that the canvas was perceived positively and found to possess pragmatic qualities by both the novices and the experts, a valuable attribute for an education tool for engineers. Overall, the experts report a more positive perception of the canvas than novices. While this is probably to be expected, it also indicates for us an opportunity to further tailor the canvas for novice users, for instance by developing the educational resources around our canvas (e.g. an accompanying quick start guide). The only scale where experts rated the canvas lower than novices is the “complicated - simple” scale. We relate this to the fact that experts had much less time to practice with the canvas than novices.
Most of the novices provided a description of the canvas, with mostly positive responses such as: “A simple model to assess complex 'blurry' topics”, “Tool to help you remember/realize the different aspects of a project that you don't necessarily think of intuitively.” and “As a good way to break down and analyze the important

aspects of different phenomena". A few responses were mixed, such as: "A good tool but could be simpler." and "Complicated but interesting". Only a few experts provided a textual description of the canvas, such as "A useful thinking tool.", "Matrix for structured evaluation" or "As a useful tool to consider in teaching witch's of AI". It is interesting to note how a number of novices contrast the practicality of the canvas with the complexity and non-intuitive aspects of technology ethics, which we take as a positive indicator of the value of the canvas for educational purposes. The more mixed descriptions by novices further encourage us to refine the instructional design of our canvas and our introduction session.

*Table 1: Results of the AttrakDiff questionnaire, with differences from the neutral response (4) tested with single-sample t-tests (*** for p < .001, ** for p < .01 and * for p <.05).*

	Negative pole (1)	**Positive pole (7)**		**Novices (N=26)**	**Experts (N=16)**
Attractiveness (ATT)	Bad	Good	Mean (SD)	**5.92***** (1.12)	**6.44***** (0.81)
	Ugly	Attractive	Mean (SD)	4.5 (1.57)	5.56 (1.21)
Hedonic Quality - Identity (HQ-I)	Unimaginative	Imaginative	Mean (SD)	5.35 (1.26)	6.00 (0.89)
	Dull	Captivating	Mean (SD)	5.23 (1.61)	6.25 (0.58)
Hedonic Quality - Stimulation (HQ-S)	Tacky	Stylish	Mean (SD)	5.12 (1.48)	**5.81**** (1.05)
	Cheap	Premium	Mean (SD)	4.92 (1.38)	5.81 (1.11)

	Complicated	Simple	Mean (SD)	5 (1.10)	4.31 (1.54)
	Impractical	Practical	Mean (SD)	**5.35*** (1.44)	**6.06***** (0.85)
	Useless	Useful	Mean (SD)	**5.84***** (1.25)	**6.50***** (0.52)

4.3 Results: quality of the session and utility judgements

The perceptions of novices and experts about the facilitation of the sessions are illustrated in questions 1 to 4 of Figure 2. The majority of participants agreed or strongly agreed with all the positive statements. Notably, 95.9% of novices and 100% of experts found the session good. Experts were a bit less positive than novices on the time allowed for questions, which we relate to the relative short duration of the workshop compared to the course.

Utility judgements of the participants are represented in questions 5 to 7 of Figure 2. Participant's evaluation of the usefulness of the session is positive with 75% of novices and 87.6% of experts agreeing or strongly agreeing. A high proportion of participants (66.6% of novices and 81.3% of experts) also reported they were likely to apply what they had learned into other contexts, which is a positive indicator of both learning and transfer (Alliger et al. 1997). Finally, the majority of respondents (62.5% of novices and 75% of experts) indicated they would like to have access to the canvas for other tasks. While this evaluation is promising, we observe that novices are overall less positive in their utility judgment than experts. This is to be contrasted with the results in terms of learning outcomes, where novices scored an average grade of 74%. Their less positive utility judgments might be due to the fact that, at the time of the session, they had not yet started to work on their course project and might not have directly seen how to apply the canvas in a concrete context. If that explanation proves to be correct, it would underline the importance of combining such an ethical canvas session with a concrete real-life project.

Novices (N = 26) **Experts (N = 16)**

Figure 2: Results of the questionnaire (4-item Likert scale) on the perceptions about the session (questions 1 to 4) and utility judgements on the canvas (questions 5 to 7).

5 SUMMARY AND ACKNOWLEDGEMENTS

In this paper, we address the issue of ethical debt by proposing a canvas for engineers to analyze more systematically the ethical risks with a digital solution at design, development or use time. Our canvas includes six ethical lenses (beneficence, non-maleficence, privacy, fairness, sustainability and empowerment) that are specific to the digital domain and implement a benefit-risk analysis framework. We presented an overview of the literature behind our approach as well as a preliminary evaluation of our canvas by engineering ethics novices and experts. The results proved positive, our canvas being perceived as practical and useful by participants, which is promising for use in engineering education. We plan to further refine our instructional resources around the canvas to provide users with more scaffolding, and to further evaluate how this canvas can be used in various settings.

Keywords: *electromobility, development of a new international study program, issues of non-EU students*

ABSTRACT

This practice paper presents the issues and solutions in introducing a new international engineering study program at a German university that attracts especially non-European students. The master's program electromobility with the four majors Artificial Intelligence and Autonomous Driving, Connectivity, E-Powertrain and Sustainable Mobility & Production Technology was newly introduced in the winter semester 2022/23. It combines the expertise of all engineering departments like mechanical engineering, electrical engineering, computer science and artificial intelligence, materials science and chemical engineering to offer a

[1] *Corresponding Author: oliver.kreis@fau.de*

modern and attractive engineering education for sustainability in an ecologic and economic important field. The high amount of applications with more than 1600 applicants per semester shows the high visibility and attraction of this study program. As the international master’s program is offered in English language, especially students e.g. from India, Pakistan or Bangladesh who already have a bachelor’s degree taught in English language are interested in this program. The selection of future students out of a high number of applications is challenging, while this process has to be completed in a very short period of time. With this high number of international students, further issues occur regarding visa application, housing and other organizational aspects. Practical solutions are presented in this paper that lead to transferable recommendations for the future design of such large-scale study programs for other universities.

1 INTRODUCTION

1.1 Current trends for the future of mobility

One of the greatest challenges in this century is the global climate change that affects people and their environment all around the world to varying degrees and demands new research projects from various disciplines. E-mobility is a key technology for climate-friendly mobility. The discussion about banning internal combustion engines in the European Union by 2035 shows how important these alternative drives will be for the future of mobility. Along with research, education must also be adapted to changing issues. The study program e-mobility matches these current trends and was developed as an international "pilot study program" starting in winter semester 2022/23. The international orientation may lead to enhanced cooperation between different nations. Furthermore, international students are welcome to stay and work in Germany after they will have finished their studies. This may counteract the shortage of skilled workers that employers are facing in the German industry.

1.2 Setting up a new international pilot study program in e-mobility

A survey of common literature on this topic lead to a study of the global management consulting firm McKinsey & Company [1] that identified four trends in the field of mobility. These are Autonomous driving, Connected cars, Electrified vehicles and Shared mobility. Although e-mobility is a megatrend, dedicated study programs "e-mobility" (not just "automotive engineering" with a major in electrical driving) are relatively rare at German universities. The homepage "studienwahl.de" is the official information portal of the Federal Republic of Germany for study programs. It lists only about 10 universities in Germany with a dedicated e-mobility master's program and most of them are in German language [2]. Considering the curricula and competence profiles of these study programs and especially based on the McKinsey study [1], the Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU) decided to develop its new study program e-mobility with the four majors Artificial Intelligence (AI) & Autonomous Driving, Connectivity, E-Powertrain and Sustainable Mobility & Production Technology [3]. Referring to the existing curricula in e-mobility in Germany, the study program also comprises competencies in the field of mechanical and automotive engineering, electrical engineering, computer science, artificial intelligence and materials science in fundamental courses. As e-mobility is an interdisciplinary field, all departments from the faculty of engineering are involved.

2 METHODOLOGY

The methodology presented in this paper consists of the following steps:

1. Conception and implementation of the new pilot study program e-mobility
2. Identifying common issues of the first two student cohorts
   (winter semester 2022/23 and summer semester 2023)
3. Structuring of the common issues in research questions (RQ)
4. Answering the research questions with transferable solutions

The following research questions according to step 3 were derived from the issues to structure the elaborated knowledge. This leads to solutions that are transferable to similar problems at other universities within and beyond the SEFI community:

- RQ1: How can the popularity for newly established international study programs be increased worldwide?
- RQ2: What evaluation options are suitable for admission in the case of large application numbers?
- RQ3: Which issues occur especially for non-EU-students and how can you solve them?

3 RESULTS: ISSUES AND SOLUTIONS

3.1 Gaining visibility and attractiveness (RQ1)

While the bachelor program is offered in German language, the international master’s program was designed bilingual, so students can choose to study in German or in English language. Due to the offered program in English, international students were expected to be attracted, here especially applicants who already studied in English during their bachelor’s degree. These students are typically from countries like India, Pakistan or Bangladesh and usually have a very good knowledge of English. When opening the application phase for the new study program in spring/summer 2022, the FAU did not expect more than 300 applications for the international master’s program in the first semester. From experiences with new study programs in German language it was known that it takes up to 1-2 years, until these new study programs are renowned in the target group. Beside information about the new study program at the university study homepages, the following measures were conducted to increase popularity:

- "Premium entry in International programs in Germany" was offered at DAAD (German Academic Exchange Service) [4].
- The structure of the study program with some majors in mechanical engineering, electrical engineering or in AI opened up a wide field of applications from bachelor graduates, mostly in mechanical, electrical, vehicle or automotive engineering.
- A study start is offered not only once a year, but in every semester (see also Table 1).

Fig. 1 shows the development of numbers of applications for the international master’s program. The mentioned measures were suitable to gain visibility and attractiveness. Especially, the DAAD premium entry was very successful to attract students. All these measures resulted in a high number of applications in the first year that raised even more in the following semesters. In the upcoming winter semester 2023/24 there are even more applications expected. Currently, an average of 20% of the applicants get an admission to the master’s program. In the past semesters, most of the admitted applicants decided to start their studies resulting in high numbers of freshmen of about 200-450.

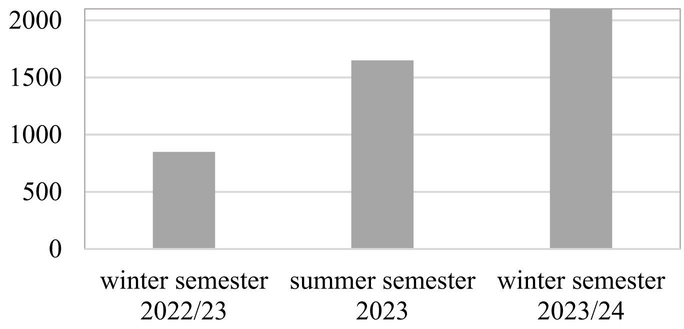

Fig. 1. Development of numbers of applications from winter semester 2022/23 to winter semester 2023/24

3.2 Suitable evaluation options for admission in case of large application numbers (RQ2)

When the new study program was introduced, there was a high level of uncertainty about the number of prospective applicants. Furthermore, it was not clear, how many of the admitted applicants would enroll in the program. The transition from paper applications to online applications was performed at the university during the Covid pandemic, resulting in a university-wide doubling of applications for international study programs.

Due to the high number of applications, individual interviews could not be conducted. Furthermore, tests in presence could not be offered due to the high percentage of non-EU-applicants. Therefore, the evaluation process is performed mainly based on the submitted documents. Since the applicants not only come from different countries and universities but also apply with different bachelor's degrees e.g. in mechanical or electrical engineering, a suitable evaluation approach has to be set up to compare the qualifications and achievements of the applicants. Therefore, the evaluation committee had to deal with the following aspects:

- Comparison of achieved modules that are relevant for the master's program with the bachelor program e-mobility of FAU
- Conversion of grades from other countries to the German university grading system
- Language certificates and proficiency tests to assure good knowledge in English (Level C1 in the Common European Framework of Reference (CEFR))
- Admission tests (open book or proctored)
- International comparisons and rankings to evaluate degrees from different universities and countries
- Further qualifications e.g. work experiences, motivation
- Examination of admission with conditional modules that must be completed as part of the master's program

The evaluation procedure comprises a formal check by the master’s office of FAU and a professional review by the evaluation committee of the study program at the department. The application and evaluation procedure is shown in Fig. 2, starting with the preparation and submission of the application by the applicant.

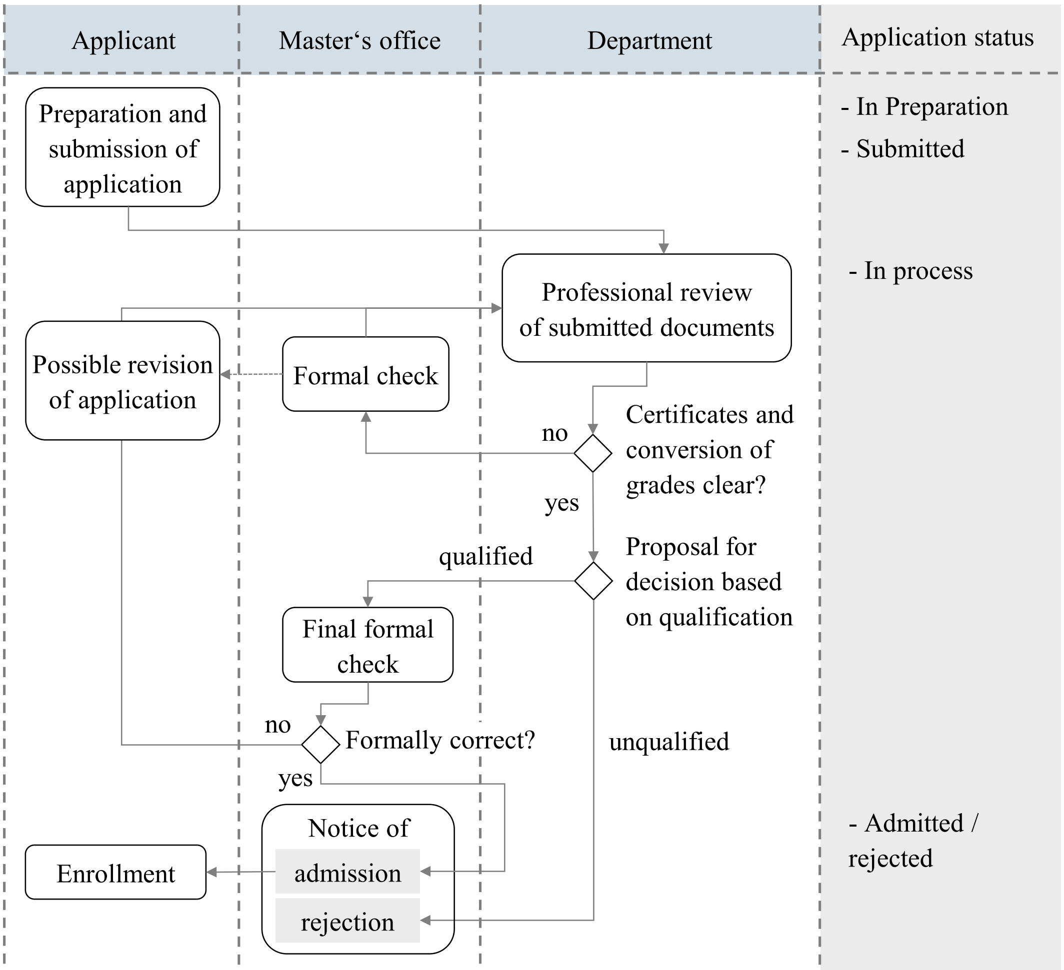

Fig. 2: Application and evaluation process for the international master’s program

The application numbers are very high, most of the applicants (>85%) submit their application formally correctly and an average of only about 20% of the applicants currently are accepted in the professional review due to the high requirements for study entry. Therefore, the professional review is performed in the first evaluation step **before** the formal review by the university-wide master's office. Only in case of unclear formal issues, e.g. unclear submitted certificates or false conversion of grades, a request for formal check is sent to the master’s office as first step of the evaluation. In that case, the formal check is done already at this point in the evaluation process to enable appropriate professional evaluation by the committee at the department. After the professional review, the evaluation committee makes a proposal for decision. If the evaluation shows that the applicant is not qualified, there will be a rejection and no further formal checking is necessary. If the committee decides that the applicant is qualified for the master’s degree, there is a final formal check before the applicant will receive the notice of admission and will then be able to enroll in the study program.

The advantage of this procedure is that the master’s office does not need to check every application formally. The formal check is only done after a request or for those applicants who are qualified based on the evaluation at the department. Especially in the case of high number of applications, this is an appropriate way to relieve the master’s office.

3.3 Issues and solutions that occur especially for non-EU-students (RQ3)

Major problems occurred especially for non-EU-students regarding the application for visa and entry to Germany. It has to be considered that applicants often have to wait for several months to get an appointment at their embassies. In the first semesters, many admissions were issued at too short notice. Therefore, the application period will start and end earlier from this semester on so that the committee is able to evaluate the applications earlier. Non-EU-students will need at least four months for preparation, visa acquisition and finding housing. Another way to speed up visa processes is that the master's office informs the DAAD about admitted applicants regularly. Students from countries like India or China need a certificate from the Academic Evaluation Center (in German: "Akademische Prüfstelle (APS)"). The APS certificate is a mandatory part of the documents that have to be submitted for visa applications. Therefore, already admitted applicants will be prioritized for their APS certificate in the German embassies.

Many students were not able to arrive in time in the first semesters. Therefore, as a pilot program, the study program offers many lectures online so that the students were able to start studying while still waiting for their visa. It took great efforts to assemble enough online classes in all of the four majors. As exams are usually taken in presence, these students need to arrive in Germany until the exam period starts at the end of their first semester. If they will not be able to arrive, they may de-register and apply again for the upcoming semester. Anyway, they will be able to take the exams in the next semester, as exams are usually offered twice a year in both winter and summer semester.

Finding accommodation in cities with more than 100 000 inhabitants is challenging, especially if it has to be completed in a short period of time. It might be easier for students to find accommodation in summer semester, as in general most of the students, especially bachelor students, start studying in winter semester.

There are some advantages and disadvantages of a study start in summer semester as shown in Table 1. The advantages regarding the flexibility and attractiveness of the study program (see also section 2.1) and finding housing were already mentioned. Especially these two aspects contributed to the decision to offer an additional study start in summer semester. In addition, the administration tasks will be spread over the whole year. The main disadvantage of a study start in summer semester in general is that it is often not possible for bachelor’s programs with their relatively fixed structure, e.g. Math 1 followed by Math 2 followed by Math 3. As master’s programs often have more flexible structures, it is easier to offer a summer start there.

Table 1. Pro’s and Con’s for additional study start in summer semester

Advantages	Disadvantages
• More students are attracted as they do not have to wait until the next winter semester if they want to study in a master’s program • Finding student housing might get easier as the students do not compete with bachelor’s freshmen who start to study in winter semester • The tasks for administration of the applications are spread over the whole year	• Difficult to realize in bachelor’s programs, where many modules build on each other, while the realization is much easier in master’s programs with more flexible study structures • Applications and study information events must be handled each semester

Especially international students have a lot of questions regarding their studies in a foreign country that may differ in organization of their previous studies. Therefore, it is necessary to give detailed advice on the procedures, their studies and general issues.

4 SUMMARY

Based on the practical experience with the new international pilot study program, issues and solutions were discussed in this paper. The following conclusions are drawn that should be taken into account when planning and setting up a new international study program:

- Global trends and interdisciplinary research areas affect the popularity of international study programs. Different majors in a master’s program open up the possibility for applications from different bachelor’s programs.
- The evaluation procedure has to be suitable for the respective number of applicants. With a high number of applications, the professional review is performed first; a full formal check is performed later only if necessary.
- An early start and end date of the application period is necessary to issue admissions early enough, so that foreign students will have a chance to prepare for their studies at the university. Non-EU students need at least four months for visa application for Germany.
- A study start twice a year (each semester) is recommended if the structure of the study program allows it.

ABSTRACT

Engineers need to be socially responsible, ethically aware and deliver positive contributions to the wicked problems[2] of today's global challenges. In navigating these challenges, being able to reflect is a necessary prerequisite. But if we simply ask students reflective questions, they tend to give us mostly socially desirable answers. Our university initiated an institute-wide program focused on creating learning experiences and environments for transformative reflection instead of superficial reflection. In this paper we present design principles for transformative reflection based on a literature overview and the program's accumulated experience. The principles are I) Six domains for reflection on engineering issues, II) The differentiation between the internal and external perspectives, III) Our approach to

[1] *Corresponding Author: P.E.A.Hermsen@tudelft.nl*
[2] The term 'wicked problem' refers to that class of social system problems which are ill-formulated, where the information is confusing, where there are many clients and decision makers with conflicting values, and where the ramifications in the whole system are thoroughly confusing (Churchman, 1967).

design for context-specificity of transformative reflective experiences, and IV) Four mechanisms that foster transformative reflection.

1 INTRODUCTION

Our complex, fast-changing world is intertwined with technology (Australian Council of Engineering Deans 2021) and our planet and humankind are facing many challenges, including climate change, pollution, social injustice, energy transition, affordable healthcare, etc. (Gürdür Broo, Kaynak, and Sait, 2022). Engineers are part of the multidisciplinary teams that will address such challenges. However, successful team members require a skillset that has not been strongly considered in engineering education (Hirsch and McKenna 2008; Gürdür Broo, Kaynak, and Sait 2022; Schuelke-Leech 2020). Transversal skills deemed important for teamwork such as communication found their way into engineering curricula, yet skills such as reflection, resilience, or the ability to reassess choices if a situation changes, awareness of ethics, social injustice, bias, and unintended implications of engineering practice have not.

Schön introduced the concept of reflection in the broader academic discourse with his seminal book on reflective practitioners in 1983 and the concept has been "widely and diversely used" (Kember et al. 2008, p 369). Reflection is directly related to self-awareness, to improving learning outcomes, to developing professionally and to understanding others (Chan & Lee, 2021). Mello and Wattret (2021) postulate that reflection is a conditional skill that enables students to develop other transversal skills, such as resilience and communication skills. The call to embed reflection in engineering curricula has been explicitly stated by authors such as Turns et al. (2014), and Chan and Lee (2021), or implicitly assumed by other sources such as the MIT mission statement that includes reflection as an implicit prerequisite for solving the global challenges (MIT, 2022) and the TU Delft criteria for Bachelor programs (Meijers et al, 2005). In this paper we present the first steps in creating an institution-wide program to develop integrations for reflection in the curriculum. We present a literature overview on barriers to implementing reflection, which we complement with our own experiences and reflections, and we present instructional design principles for transformative reflection.

2 REFLECTION IN ENGINEERING EDUCATION: EASIER SAID THAN DONE

There are many reasons why embedding reflection in engineering curricula is challenging. In this section we present a literature overview (Grant and Booth, 2009) on why it is challenging and what barriers get in the way. We complement the literature overview with outcomes of participatory research with engineering educators in our institution in 2021 and 2022 (Hermsen et al, 2022).

Reflection can mean many different things in many different contexts, and different fields of application have different definitions (Chan, Wong, and Luo 2021; Akbari 2007; Cotton 2001; Tsingos, Bosnic-Anticevich, and Smith 2014; LaBoskey 1994). Reflection involves carefully evaluating and making sense of one's behavior, beliefs, and perspectives , which can lead to both useful insights and uncomfortable realizations of weaknesses or mistakes (Chan, Wong, and Luo 2021; Mezirow 1998; Boud, Keogh, and Walker 1985; Grant, Franklin, and Langford 2002). Facing personal aspects can be experienced as difficult and even threatening, causing self-doubt and non-constructive self judgments (Hobbs 2007; Bharuthram 2018). Lönngren (2017) stated that reflection is often considered to be in tension with the technology-oriented culture of engineering sciences, which prioritizes measurable outcomes and linear problem-solving (see also Schuelke-Leech, 2020). This conflict is caused because reflection involves abstract connections and perspective-taking, and is often associated with dealing with emotions and vulnerability. As a result, many engineers perceive time spent on reflection as time lost on disciplinary knowledge (Hobbs 2007; Chan, Wong, and Luo 2021; Bharuthram 2018). This prospect may make instructors reluctant to reflect or incorporate reflection into their teaching and have students engage with it.

Meaningful reflection does not happen by itself: Meijers and Mittendorf (2017) found that, in spite of teachers' attention to reflection in assignments, students often provide socially desirable responses and struggle to find meaning in reflective exercises if they receive little instruction or guidance. In technical subjects it is important to scaffold, and the same goes for learning to reflect, as reflection without instruction and practice results in superficial reflections that have a minor impact on learning at best (McIntosh 2010; Ryan 2013). Instructors and students find it challenging to integrate reflection in daily practice and provide meaningful guidance through the process (McIntosh 2010; Ryan 2013). Students experience reflection-fatigue when they are asked to reflect on a regular basis (Kinkhorst 2010) or even turn into ‘reflective zombies’, which happens when reflection becomes superficial, repetitive, unproductive or even counterproductive (De la Croix and Veen 2018; Bharuthram 2018).

Although there is a considerable body of knowledge on the topic of reflection, authors often fail to describe how their design and application of reflection have been tailored to a specific context. This makes it hard for instructors to understand how to take contextual factors into account in their own courses. Some publications on reflection are highly theoretical and strongly rooted in philosophy, while other publications are very practical, yet often do not apply to the instructor’s context. Assignments for meaningful reflection need to hit a sweet spot, as assignments need to have a certain level of practicality for students to be able to relate to it, yet by making it too practical it can easily end up becoming a tick-box activity, where the recording of compliance with assessment requirements is more prevalent than actual learning (Barak 2006; Platt 2014).

There are practical barriers to implementation of reflection in coursework. Searches for articles on reflection in (engineering) education tend to yield many hits that include publications on education as well as the subject of reflection, which makes it overwhelming for laypersons to find appropriate resources. From an instructional design perspective, there are many supporting or limiting factors for (classroom) assignments: how big is the group, what year are students in, how familiar are these students with reflection, what kind of learning activity is it part of? Is the physical space safe and inviting, are there any language barriers present, when should reflection be scheduled, and will there be opportunities to provide feedback and debriefing to the reflection exercises? Due to all these challenges instructors may lack confidence or feel resentful about delivering guidance for reflection, as it adds to their workload or ‘distracts’ them from research practice (Beard, Clegg, and Smith 2007; Platt 2014), while the benefits are not always clear. Creating meaningful opportunities for students to reflect is hard, and real, visible impact for students is far from guaranteed. Without tackling these challenges reflection will remain an afterthought in engineering education, rather than an integrated activity.

3 THREE MAIN ELEMENTS OF STRUCTURAL ATTENTION FOR REFLECTION

Schaepkens and Lijster (2022) argue that meaningful reflection needs to bridge two gaps: 1) the gap between theory and practice and 2) the gap between an individual and their community (p.3). Schaepker and Lijster follow Kant in arguing that reflection resists systemization and can not be taught: it can only be practiced as reflection needs a context and there are no definite rules that can address all contexts. Additionally, individuals and communities always change, so the gap between individual and communal sense requires a continuous dialogue, not a set of rules. However, without structural attention for practicing reflection students will not develop skills to reflect on their praxis in a meaningful way. Our university initiated an institution-wide program that recognizes the importance of reflection and aims to embed meaningful reflection in our engineering curricula. In this section we describe four main elements of our program.

Element 1: There are many ways to do reflection
Within the program we do not advocate 'one right way' for reflection. Instead, we aim to create a vision of the possible role and use of reflection in engineering education that leaves enough room for instructors to adapt to specific contexts. The program aims to be supportive, not prescriptive, to instructors who wish to integrate reflection in their courses. We see reflection as a process in which engineers stop and take time to use their thoughts and feelings to make sense of an experience or issues, and to yield insight into themselves and into how they relate to the world around them so that they can grow and/or change their actions. There is no shortage of literature about how to “do” reflection, originating from a variety of research fields, such as education, psychology, healthcare, management and philosophy (Mina, Cowan, and Heywood 2015; Fleck and Fitzpatrick 2010; Gordijn et al. 2018; Keestra 2017; Marshall 2019). We do not oppose any models these authors propose and our practice of reflection is not a substitute. Yet, instead of prescribing one way to ‘do’ reflection, we provide information, structure, vocabulary, and awareness to instructors to make an informed choice in the use and purpose of reflection.

Element 2: Six domains of reflection
We frame reflection in the context of engineering education and distinguishing six domains to reflect on. That way reflection becomes a concept that instructors and students can grasp more easily. The six domains were identified through an institution-wide exploration of what reflection is (Hermsen et al., 2022). These six domains are:
1 - Society: reflection on social themes and challenges. For example, climate change, inclusion and equity, affordable healthcare, sustainable infrastructure and mobility, energy transition, circular economy, and others.
2 - Product: reflection on the various stages of developed models, prototypes, policies, procedures, services and /or research. For example, on weighing requirements, balancing impact, the value, and limitations, etc.

3 - Process: reflection on the (sub)conscious choices made in the process and the way they influence outcome. For example: going over activities, looking at blind spots and assumptions, examining successes and mistakes.
4 - Interaction and collaboration: reflection on interactions and collaboration with peers or supervisors. Reflection on for example to understand others, prevent, manage, and solve conflicts.
5 - Learning: reflection on learning strategies, assessments, ambitions, attitudes, targets, motivation, personal development, and ownership of learning.
6 - Oneself: reflection on one's behavior and perceived identity, for example on personal contexts, standards, beliefs, values, convictions, biases, and privileges.
The domains help structure reflection and facilitate comprehension rather than create isolated areas that confine reflection. In practice these domains are interwoven, and sometimes overlap. Labeling the domains provides vocabulary to enable comprehensive dialogue on what to reflect on.
The domains are depicted in Figure 1A.

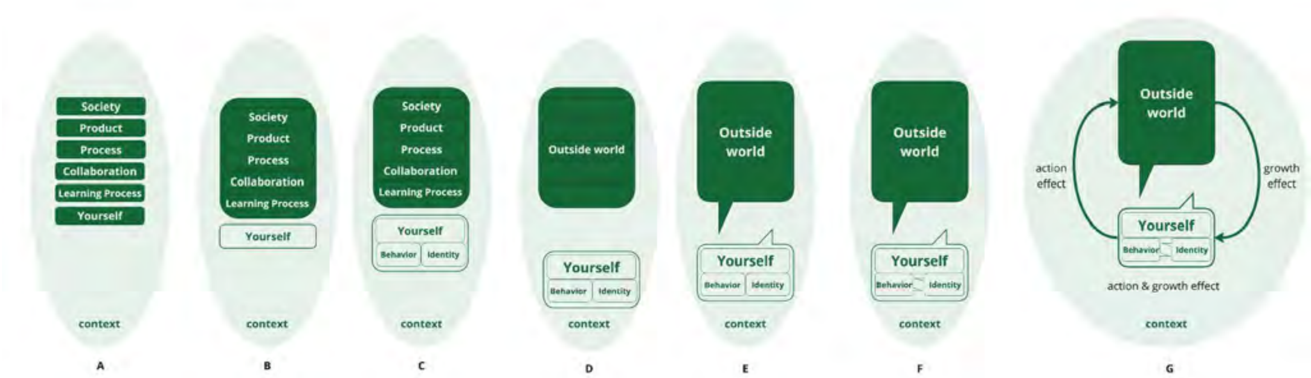

Figure 1 Visualization of (transformative) reflection

Element 3: Contextualization of reflection
Meaningful reflection happens in a context, not in a vacuum. As reflection needs to bridge the gap between the individual and their community it is important to be aware of knowledge, experience, mental models, interpretations, norms, culture, and values assigned to reflection by individuals, sections, departments, faculties, and educational programs that are present in the community. Leaders who prioritize reflection and create space for experimentation and for learning from failure foster a different environment than those who enforce strict control (Maarel 2016; Laloux 2016). For example, reflection on mistakes will be different in a department that frequently discusses mistakes, compared to a department that never discusses them. Finally, there are many practical context-dependent factors to take into account, as discussed above. These include, yet are not limited to, creating time, space, and a setting to create conditions for meaningful reflection to happen.

Element 4: Transformative reflection
Thirdly, we aspire to deepen reflection into *transformative* reflection. As mentioned before, superficial reflection is not uncommon, yet we aim for reflection that is able to initiate change, by contextualizing, enriching, and augmenting the reflective activity. The word 'transformative' is informed by the Oxford Advanced Learners' Dictionary that describes it as "causing or able to cause change", and by scholars like Kitchenham and Mezirow who have worked on transformative learning (Kitchenham

2008; Mezirow 2000) and contributions to the Journal of Transformative Learning, e.g. Minnes et al. (2018) and Scheele (2015). Based on these contributions we see transformative reflection as going through a process of reflection that is causing or is able to cause change in learners' points of view, frames of reference or habits of mind and how learners experience, conceptualize and interact with the world. Change can be small; for example, something suddenly making sense. Change can be big(ger); for example, a behavioral change is initiated. Transformative reflection can occur naturally or through a designated activity, yet not all reflective exercises we design for students are transformative (de la Croix and Veen 2018).

4 TRANSFORMATIVE REFLECTION IN PRACTICE

Transformative reflection cannot be forced, yet we find that we can design meaningful activities that create opportunities for this type of learning. We established three steps that need to be present in meaningful reflection activities.

Step 1: Distinguish and link multiple reflection perspectives
Figure 1B shows that our external reflection perspective is influenced by our internal reflective perspective. If we relate to or interact with the world, we always take ourselves with us. The external perspective is shaped by community expectations and outside requirements. Code-switching[3] (McCluney et al. 2019) is an example that demonstrates this principle. One consciously or subconsciously adapts one's behaviour to fit in different social or cultural situations. Figure 1C shows that the internal perspective consists of our perceived identity and our behaviour. Identity and behaviour may not always align and can vary depending on the situation. To design a transformative and reflective activity, it is important to incorporate both the personal perspective (ourselves) and perspectives that exist in the outside world.
[2] Code switching is the way in which a member of an underrepresented group (consciously or unconsciously) adjusts their language, syntax, grammatical structure, behavior, and appearance to fit into the dominant culture.

Step 2: Facilitate a dialogue between internal and external perspectives.
Understanding and seeing links between the six reflection domains and reflection perspectives is not enough. For reflection to become meaningful or transformative, we need a process that *facilitates an interaction* between ourselves and our perspective and the world outside of us: we create this interaction using the following four mechanisms.

Step 2.1: Create distance between ourselves and other domains.
First, we disentangle the domain of "Self" from the five other domains and create distance. By doing this we create the opportunity to define internal and external perspectives. Separating the internal perspective from external expectations creates space to consider multiple external aspects without the need to deal with them immediately. This also creates space to look at ourselves without expectations or judgements that are imposed by yourself or the world outside.

Step 2.2: Point out the gap between the internal and external perspectives and review each in isolation.
Now that we have created distance between the outside perspectives and ourselves, there is space to explore multiple possible interpretations or perspectives on the

issue at hand with a curious and open mind. Questions to explore include: what are the ways that other people regard the situation? How do other people or cultures deal with this? What are blindspots? What could be unintended side effects of choices made? How did the other person experience the collaboration? What other things could be learned in this course? Could there be different intentions than mine? Or: if I try to look at myself without judgment, what do I see? Mechanisms 2.1 And 2.2 are represented in Figure 1D.

Step 2.3: Create a 'dialogue' (tension) between inner and outer perspective.
Switching between internal and external perspectives creates a 'dialogue' which can provide a new perspective, or may provide insight into your position. This insight might change the way you perceived something previously. For example: suppose you were annoyed that one group member worked fewer hours than the others. By exploring reasonable causes of this behaviour, you might realize that there are many reasons for this behaviour to be acceptable, e.g. suffering a loss, being sick, taking care of family, having financial problems etc. This might not only give you a new perspective on the conflict, yet it might also give you some insight in that having no external responsibilities or no financial problems are a privilege that you enjoy. Subsequently, this insight might affect the way you handle a similar conflict; you might enquire with a person about the reasons behind it and be more empathetic. Going back and forth, adopting other views or perspectives, provides insight into the unknown parts of you or any blind spots (Luft and Ingham 1955) and it will change the way you relate to the outside world. This mechanism is represented in Figure 1E.

Step 2.4: Creating a second 'dialogue' between identity and behaviour
Transformative reflection requires a second dialogue between identity and behaviour. By examining and addressing the way we see ourselves in relation to our actions, we gain insights into our values, beliefs, and norms and/or in new ways to move forward. Building on the example of a group project conflict: the insight in that your work behaviour in this group is not only the result of your hard work, yet also of your financial and social circumstances might warrant the belief you are a 'hard worker', and it might also change the way you act when others are not pulling their weight. Or it might point you towards the realization you find it really difficult to act in such situations and that you need to work on your communication skills. This mechanism is represented in Figure 1F.

Step 3: Appreciate reflection for action and growth.
As the examples in the descriptions of the mechanisms illustrate, we differentiate between two reflection effects: reflection for action (What can I do differently?) and reflection for growth (What do I learn about myself or about how I see the world around me?) Taking time within the reflection activity to acknowledge the effect that the reflection has, supports consolidation of that effect. This mechanism is represented in Figure 1G.

5 DISCUSSION AND CONCLUSIONS

Today's wicked problems require engineers to be able to deal with the unknown and work across disciplines. This requires skills beyond the traditional boundaries of the engineering domain, such as social and ethical awareness, empathy and collaborative skills. Reflection is a prerequisite skill to those transversal skills, and

reflective skills enable engineers to notice and adapt to what is needed. Although reflection is widely regarded as important for engineers, its applications and the way it is taught generally has a narrow scope. Moreover, reflection skills are assumed to develop naturally. However, we found reflection requires structured attention, and specific instructional design.
We contextualize reflection as a tool in engineering and present prerequisites and mechanisms to design for deep, transformative reflection. Our approach complements existing reflection models. We attempt to initiate a fundamental change in how we design reflection in (engineering) education by moving towards emergence, instead of plug-and-play best practices. The six domains, perspectives and effects of reflection help engineering students and instructors understand how our perspectives influence how we relate to and influence the world.

Intuitively, the combination of reflection on the outside world to improve action fits well with engineers, as engineers tend to be analytical 'problem solvers', creators, designers and manufacturers. Contemplative reflection of the internal perspective for personal growth might be less intuitive, yet is crucial to develop proficiency in this skill (Hermsen 2022; Marshall 2019; Schön 1983).

We are aware many authors and practitioners already use elements of reflection we mentioned in this contribution. However, to our knowledge, there are no other publications that look at the contextualisation of reflection as a tool, or describe instructional design principles for transformative reflection. There might be other ways to design transformative reflection, yet the work presented here is our attempt to facilitate the process. The presented construct provides structure and key mechanisms for designing transformative reflection. However, it is not a foolproof step-by-step plan for designing effective reflective activities. Further experimentation with the model is needed.

The narrative feedback from students and instructors who participated in transformative experiential education is highly positive. They gain insights into themselves and others and see new ways forward and they value reflection higher. We are currently studying the impact of our transformative education in systematic ways. The work presented in this paper aims to raise discussion on the role of reflection in engineering education and leaves us to question how to scale up and make transformative reflection accessible to instructors.

Conference Key Areas: *Addressing the challenges of Climate Change and Sustainability, Embedding Sustainability and Ethics in the Curriculum*
Keywords: *Authentic assessment, energy transition, sustainability leadership, role-play, experiential learning*

ABSTRACT

To lead the energy transition, effective sustainability leadership requires a spectrum of skills, knowledge and understanding across technical, financial and even political disciplines. An innovative, authentic learning initiative has been designed and implemented in which Master of Sustainable Energy students conducted team-based role-playing activities, responding to a realistic, hypothetical energy policy scenario in the form of a government announcement and other mock collateral. Groups were assigned the personas of a range of industry stakeholders and prepared presentations (and accompanying media statements and position papers) for a mock online media conference. The initiative leveraged the diversity of the cohort, enabling constructive interactions and an appreciation of the impacts of energy policy on a variety of organisations and wider society. Entry and exit surveys affirmed that participants gained a deeper understanding of key issues, constraints, alternative views and approaches involved in navigating the policy pathways to sustainability. The teaching staff also observed a high level of student engagement. Challenges of group dynamics and teaching effort were felt to be outweighed by the benefits reaped by students, particularly in terms of deeper conceptual knowledge and an understanding of perspectives in the energy transition. The case study also found that the online nature of the media conference enhanced student innovation and engagement. The framework of the case study may nudge other educators towards greater use of role-playing activities in sustainability leadership pedagogy.

1 INTRODUCTION

1.1 Sustainability Leadership in the Energy Transition

The transition to sustainable energy, as part of a global net-zero carbon future, can be characterized as a “wicked” issue, involving both conflicts and conciliation. Motivated and diverse leaders are required, adept in their ability to analyse, at disparate scales, the trade-offs between energy security, equity and sustainability. In this setting, a distinctive theory and practice of sustainability leadership has emerged (Shriberg and MacDonald 2013) This represents a more inclusive, balanced, and deliberate process of influence that aims to deliver direction, alignment, and commitment to address social, environmental, and economic issues (Bickley et al. 2013). The principles of sustainability leadership highlight the importance of cross-boundary networks and engagement with stakeholder perspectives, as well as systems thinking and facilitation skills to respond to complexity (Allen et al. 2014). Teaching these skills to new sustainability leaders who are involved in the energy transition requires innovative higher education pedagogies (Beagon et al. 2021) with a focus on authenticity and multiple perspectives.

1.2 Authentic Learning and the Use of Role-Play

Higher education curricula with a focus on sustainability leadership show a strong prevalence of project-based learning and the facilitation of interactions between participants (MacDonald and Shriberg 2016). This is often based on authentic, experiential learning, where participants are involved in realistic simulations that can be integrated into practice (Boud and Prosser 2002), and contextualised against delivered content and lived experience (Bartle 2015). When this is combined with group work, constituted by people with diverse backgrounds, the cross-pollination of ideas and concepts yields even deeper perspectives. The rapidly shifting landscape of the energy sector and sustainability requires knowledge and adaptable skills which are well suited to this pedagogical approach. Experiential learning coupled with the practice of reflection can cultivate deep and lifelong learning that contributes to professional practices (Ayers et al. 2020).

Role-playing is an authentic pedagogical approach identified to have high relevance for developing sustainability-related competencies (Gordon and Thomas 2018), required by graduates leading the energy transition. However, several challenges are associated with using role-playing activities, including the time required to design and deliver scenarios that both reflect the real world and engage students (Gordon and Thomas 2018). There is sparse research on role-playing activities in online and hybrid teaching settings.

1.3 Objectives of this Paper

This paper outlines a case study of a role-playing activity and its effectiveness in enhancing sustainability leadership skills. The context of the study is a course on Energy Markets, Law and Policy within the Master of Sustainable Energy, a unique multi-disciplinary program offered by the School of Chemical Engineering at The

University of Queensland. The course is delivered synchronously to both internal (on campus) and external (online) students via an intensive teaching period, followed by course assessment, including the team-based role-playing activity, which was conducted entirely online. The role-playing activity is centred around a fictitious, but credible, policy scenario, with students acting as organisations and responding via authentic channels such as media conferences and position papers.

Through anecdotal observations and longitudinal student surveys, the paper evaluates the efficacy of role-play across the dimensions of knowledge transfer, appreciation of complexity, competency to set energy policy, and consultative approach to stakeholder perspectives. The results of the case study show that the role-playing activity is very well received by students, encourages active participation and has been successful in upskilling in some of the key elements of sustainability leadership. The paper also reflects on the teaching effort required to coordinate the online activity, along with its challenges and opportunities, and provides some recommendations on its place in engineering education for sustainability.

2 METHODOLOGY

2.1 Role-Playing Activity Design and Implementation

Figure 1 presents how the program was conducted. Prior to the role-playing activity, students participated in lectures and workshops in an intensive format. In one lecture, external presenters delivered industry insights to their approach to energy policy. Students were assigned to groups by the teaching staff, with the diversity of team members being a key consideration. Each group was then assigned the persona of a distinct Australian organisation that is impacted by energy policy. They included an electricity generator, a hydrogen startup, a low-income advocacy organisation, a vertically integrated energy retailer and a think tank.

Students were provided with substantial collateral to explain the policy initiatives. The teaching staff invested substantial effort to produce mock content which replicated the format and limitations of real-world policy delivery. This included a short video announcement from the Prime Minister, a regulator's website, a branded capital raising prospectus and a ministerial press release. The materials had a consistent core message, but akin to real-world communications, the collateral contained gaps, inconsistencies and flaws. Together, the materials conveyed a hypothetical policy position to be adopted by the Australian government, which would have implications across the economy for investors, energy market participants, consumers and industry.

Groups were tasked to arrive at a position that supported the interests of their assigned organisation and stakeholders. The task required interpretation, analysis and persuasive response, conducted with an emphasis on leadership, teamwork and communication. Critically, the role-playing activity was held entirely online, via Zoom with all students present for the entirety of the activity. This facilitated a multi-perspective approach aimed at enhancing students’ sustainability leadership skills.

The role-play framework provided the scenarios for presentations and written content which constituted 50% of the students' total course marks, with an expectation that each student would contribute about 45 hours of work, although this was not monitored. Student submissions were generally of very high quality, reflecting the high engagement of the cohort and the competitive nature of group work, with some submissions exceeding teaching staff's expectations. Group deliverables were submitted two weeks after the intensive learning modules:

- A realistic, branded one-page media statement, submitted online before the presentation, and available to be read by all students.
- Submission of written well-formulated, tailored questions for each group, prepared as journalists.
- A 5-minute group presentation set in the style of an online media conference.
- A 5-10 minute response to questions.

In addition, two weeks after the media presentations, groups were required to submit a comprehensive Position Paper that further articulated organisational positions, and reflected on learnings from the presentations.

Non-presenting groups acted as the audience, role-playing as journalists attending the media conference, asking questions curated by the teaching staff. Later, groups were required to submit a position paper providing further details of the organisation's response to the policy announcement.

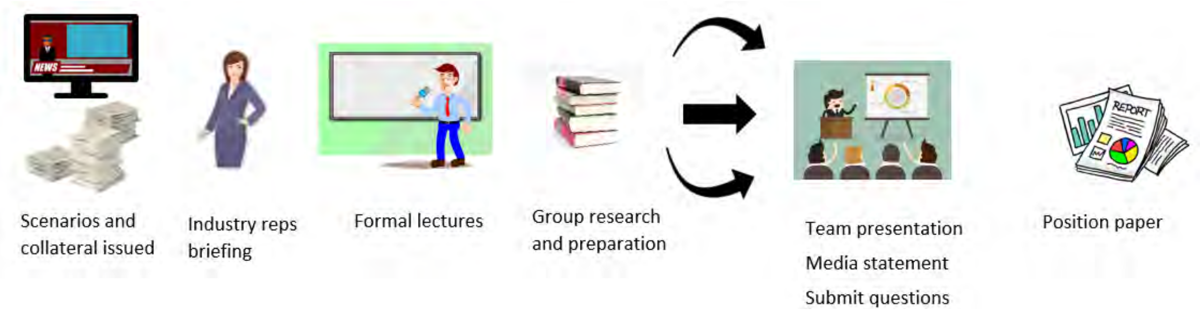

Figure 1: Learning initiative workflow

The primary learning objective of the role-playing initiative was to contextualize the core content of energy markets and policy. Secondly, students were trained in leadership through position development, team management and persuasive argument. And finally, students were afforded the opportunity to appreciate policy from alternative stakeholder perspectives. In the media presentations, groups were assessed using a marking rubric that covered all the deliverable outlined above. The Position Paper was also assessed, with further criteria on articulation of vision and references. To score well in the assessment items, a group's position required the appropriate use of facts, frameworks and underlying theories developed in the course. Groups were at liberty to agree or disagree with the proposed policies, or offer alternative policies and recommend methods for policy implementations.

2.2 Assessing Effectiveness of Learning Initiative

Direct observation, anecdotal feedback and survey instruments were used to establish if the role-playing activity enhanced sustainability leadership skills and achieved the objectives detailed in section 2.1. Positive attributes associated with experiential learning using role-playing (Boud and Prosser 2002) form qualitative and quantitative ways of measuring success.

Specifically, the assessment aimed to establish:

- Were competencies improved in sustainability knowledge and leadership?
- Did students' views about energy policy change as a result of the initiative?
- Did the initiative heighten students' engagement in the material?
- Did students value the role-playing and teamwork aspects of the activity?
- Was the learning experience compromised or enhanced by assigning students to role-play as organisations where sustainability values conflicted?

In order to assess the efficacy of the role-playing approach and to assess alignment with the project objectives, a longitudinal research approach was employed:

- A pre-course "entry" survey on content knowledge, attitudes to energy policy and leadership, using a 5-point Likert scale.
- A post-course "exit" survey consisting of the same questions, plus questions to understand changes in views, teamwork perspectives and values alignment.
- Anecdotal feedback from students and teaching staff.

Summary statistics from survey responses were derived to establish the degree to which students perceived that the learning objectives were met. A *t*-test was performed to determine the significance of changes in perceived competency upon entry and exit. Results were also segmented to determine if the cohort responded differently depending on domestic/international or full-time/part-time status. ANalysis Of VAriance was applied to establish if the survey responses were influenced by the ethical alignment between students and their organisation.

The surveys followed ethics protocols established by the Faculty of Engineering, Architecture and Information Technology at The University of Queensland. Participation in the surveys was voluntary, with clear information presented at the beginning of each survey explaining its purpose, the non-identifiable nature of any data/responses gathered and the right to withdraw from the project. The survey sought explicit consent from participants to use their data/responses for this research project. From a cohort of 60 students in 2022, 41 consenting responses were received to the pre-course survey and 31 to the post-course survey.

3 RESULTS

3.1 Student Survey Results

Content Knowledge, Attitudes to Energy Policy and Leadership

The student entry and exit surveys (Table 1) showed that the role-playing activity facilitated a vast improvement in energy policy content knowledge (Q1 - Q4). Sustainability leadership was manifest in increased confidence in 'knowing what to do' (Q6). All results were significant at the 95% level of confidence. There were no significant differences across domestic/international students or by full/part time.

Table 1. Student entry and exit surveys: self-assessment on knowledge and attitudes

(Entry N= 41), (Exit N=31). Scale 1 = Very Low to 5 = Very High	**MEAN ENTRY**	**MEAN EXIT**	**MEAN Change**
Q1. I judge my level of understanding on energy policy to be.	2.88	3.94	1.06
Q2. I know the aims of government energy policy in my jurisdiction.	3.02	3.97	0.94
Q3. I know how the government practically implements energy policy in my jurisdiction.	2.78	3.94	1.15
Q4. I understand how energy policy affects different parts of business/society	3.33	4.10	0.77
Q5. I can interpret energy policy announcements in my jurisdiction	3.10	4.13	1.03
Q6. If I personally held the responsibility to set energy policy in my jurisdiction, I would know what to do	2.51	3.74	1.23

Changes in Views

The exit survey asked students to quantify the extent to which their views on energy policy and regulation shifted as a result of their experiences during the course (Table 2). Students conveyed that the influence of energy policies extends to vastly more stakeholders in society (Q8), in a more complex manner (Q7), than they appreciated before the course.

Interestingly, responses were mixed on whether collaborative or authoritative energy policy approaches were better (Q9), with a bimodal distribution. The mean across *domestic* respondents for Q9 was 2.47 (indicating a shift to preferring more collaboration) while *international* students returned 3.47 (indicating a shift to a more authoritative approach), being a significant distinction at 95% confidence. This highlights the potential influence of culture, values and familiar government systems in forming views.

Table 2. Student exit survey: self-assessment on change in views through course

(N=31). Scale: 1 = Very Low to 5 = Very High	**MEAN**	**Stdev**
Q7. Compared to my views at the beginning of the course, I believe Energy Policy issues are less or more complex?	3.94	1.15
Q8. Compared to my views at the beginning of the course, I believe Energy Policy affects fewer/more stakeholders in society?	4.42	0.62

Q9. Compared to my views at the beginning of the course, I believe Energy Policy requires a more collaborative (1) or more authoritative (5) approach?	2.90	1.35

Teamwork and Role-Play

Exit surveys revealed the value that students placed on the role-playing and teamwork nature of the design (Table 3). The *effectiveness* response (Q10) indicates that students themselves discerned that engagement was elevated as a consequence of role-playing. The *importance* response (Q11) revealed that students recognised that the format of the initiative helped them to absorb content and acquire skills.

Table 3. Student exit survey: self-assessment on the importance of teamwork and role-play

(N=31). Scale: 1 = Very Low to 5 = Very High	**MEAN**	**Stdev**
Q10. How effective was role-playing as a learning approach to Energy Policy in this course?	4.16	0.73
Q11. How important was group work and role-playing to your learning outcomes in this course?	4.03	0.98

Values and Industry Involvement

Students were surveyed on exit to establish the degree of alignment between their personal values and the organisations that they role-played (Table 4). The positions and solutions that the groups promoted in role-play were generally aligned with their personal values (Q12), despite the fact that organisations included fossil fuel industry bodies and thermal electricity generators. The responses to Q12 and Q13 provided encouraging feedback that the emerging cohort of professionals is able to balance perspectives, including the roles of existing industrial stakeholders, as part of a sustainable energy future.

Responses to Q12 allowed us to investigate whether student engagement or other responses were systematically *lower* if students found themselves associated with an organisation whose values *disagreed* with their own. Application of ANOVA revealed there was *no evidence* of such dependence.

Responses to Q14 showed strong evidence that students would value ongoing access to a representative of their nominated organisation to guide decisions and interpretations. Our pedagogical design contemplated this feature, but for pragmatic and student equity reasons it was not instituted: it remains a possible learning enhancement in future.

Table 4. Student exit survey: self-assessment on values and industry involvement

(N = 31). Scale: 1 = Very Low to 5 = Very High	**MEAN**	**Stdev**
Q12. My personal values aligned with those of my assigned organisation/company	3.87	0.81

Q13. The position my group developed is an appropriate response for my assigned organisation/company.	4.35	0.75
Q14. How would you feel about the group project if there was a representative from the actual organisation available to answer some of your questions?	4.42	0.72

3.2 Student Anecdotal Review

Respondents offered free-text feedback on the exit survey and three main themes emerged (Table 5). Students verbally commented that the role-play was “a fun way to learn”, which was observed by the teaching staff, and supporting our assertions on student engagement.

Table 5. Student exit survey: Free text response examples

Theme	Example Comment
The role-playing format was an effective and engaging way to learn about energy policy.	*Role-play was an engaging and interesting method to discuss policy issues.*
Teamwork was a successful approach for sounding ideas and consolidating concepts.	*About the group presentation and role-play, it is a fantastic idea to engage the people with the Energy Policy. This is always a challenge because of the tough topic, and energy policy is not easy to digest and understand all the potential impacts that it could have.*
Viewing the presentations and preparing questions for other groups enabled an understanding of policy from different perspectives.	*It was good to put yourself in the company shoes then have to put yourself as a journalist to then think about questions and how the same policies affect other businesses.*

3.3 Reflections and Experiences of Project Designers

The teaching staff observed that the role-playing approach and relevance to real-world issues led to high student engagement and universal participation, which aided the teaching process. Deliverables were on par with professional standards, and the Zoom format allowed students to add flourishes, including costumes, microphone props, fake names, branding and background logos during their role-play.

Our assertions that students successfully contextualised sustainability leadership theory was based on the sophistication of responses formulated by students in presentations, both prepared and impromptu, and the way that reflections were weaved into the position papers.

Peer-based learning manifested through skills and knowledge sharing in group work, particularly supporting the less-prepared students. Group interactions reduced the volume of direct queries to the teaching staff.

However, some students provided feedback that the workload was burdensome, with high expectations. Group dynamics is always difficult in university environments, and some team disagreements were only resolved through intervention and alternative assessment paths. While disparate views added value in some groups, it could also result in irreconcilable conflict, presenting a microcosm of real-world climate politics.

Preparing the scenarios, collateral, managing groups and hosting role-play forums all add to the teaching workload. However, given the benefits to students and the positive outcomes it was felt that the initiative was worthwhile. Alternative ways of industry engagement have been documented (Thomson et al., 2021), but the balance between benefits and administrative burden is delicate.

4 DISCUSSION

Consistent with the finding of others (e.g., Gordon and Thomas, 2018), the authentic learning has proven successful as an initiative to enhance learning outcomes in sustainability leadership. The delivery model elevates student engagement, and role-playing itself acts as a training device to introduce skills such as presentation, communication and persuasive argument. The role-playing experience with authentic scenarios enables students to contextualise lived experience, contemporary current affairs and other course knowledge (Bartle, 2015).

Surveys measuring perceived competence illustrated a significant improvement in the cohort's energy policy knowledge and sustainability leadership. It is conceivable that content could still be reinforced with traditional delivery methods, but perhaps student engagement would be reduced, fewer conceptual connections would be made with the rest of the program, and real-world stakeholder perspectives would not be appreciated to the same extent.

The diverse organisations in the role-play exposed students to the vast complexity of the energy transition challenge. Entry and exit survey results confirmed significant changes in student views. Group work needs careful curating (Zou et al. 2012) and it was found some teams were unable to find conciliatory positions. Survey evidence suggests that ideological biases may be a contributing factor to group-work failure but longitudinal studies (Zou et al. 2012) suggest other pitfalls such as social loafing. Other teaching initiatives to foster teamwork (Azizan et al. 2018) have also found success as part of student-centred cooperative learning strategies.

It is worth reflecting on the limitations of role-playing. The tool simplifies complex sustainability challenges and decision-making, potentially affecting authenticity and the transferability of skills and knowledge (Kioupi et al. 2019). Role-playing activity that is executed poorly can be uncomfortable and emotionally overwhelming for some learners (Gordon and Thomas 2018) and can lead to scripted outcomes that reduce critical thinking. This study did not find any evidence of these issues, but the activity did benefit from well-prepared, realistic scenarios and collateral; a mature postgraduate cohort; and a mixed-methods approach to teaching and assessment.

Educators may encounter challenges integrating industry involvement in educational programs (Thomson et al. 2021). In this activity, it was found that corporations were protective of branding and reputation. When socialised, realistic student submissions were required to have watermarks and de-branding to ensure that they were not confused with actual corporate publications.

5 CONCLUSION

The generation of sustainability leaders who are presently emerging to guide the global energy transition has an enormous task ahead of them. To equip them only with technical and economic skills is doing a disservice to individuals operating in a highly cross-disciplinary field. This study has determined that role-playing delivers an authentic learning experience that successfully immerses students in energy policy, markets and regulations, and enables understanding and deep conceptual connections with other fields of sustainability. Importantly, the case study has shown that a multi-perspective approach can be delivered online efficiently, with high levels of student engagement and a high degree of authenticity.

While the initiative delivered successful learning outcomes, avenues for improvement have been identified. However, reflections suggest that enhancement of the resources and facilitation need to be balanced against the additional time and effort required. Future research could focus on addressing challenges including inclusivity and critical thinking, to maximise role-playing effectiveness in sustainability leadership education.

There are two main contributions emanating from our work. Firstly, the dissemination of this case study may contribute to greater consideration of the use of role-play as a rich and authentic learning experience in higher education. By documenting the approach of this case study and addressing the common perceptions of challenges and effort, the paper provides some insights to guide future educators.

Secondly, our implementation has documented the use of role-playing activities in an increasingly online, and/or hybrid learning environment. In the case study presented, the activity flourished across a student body constituted by teams who conducted group work in a hybrid format, including online sessions. While the role-playing activity itself was performed entirely online, no technical issues were encountered but some unexpected benefits were reaped in student engagement offered by the Zoom platform.

Together, these contributions may enhance the discussion on opportunities for planning and running role-play as a valuable activity for higher education in sustainability leadership. Indeed, the pedagogical approach and the assessment frameworks could be used by others to assist with more widespread implementation of this worthwhile activity.

ABSTRACT

In response to the COVID pandemic, many of our undergraduate students were supplied with custom development kits to undertake their electronic laboratory activities at home. Following our return to on-campus teaching, we plan to combine on-campus laboratory sessions with at-home experiments taking advantage of both on-campus and at-home experimental work while avoiding some of the limitations experienced during remote teaching. The goal is to embed active learning as a key part of a long-term strategy to enable students to better manage their learning and to maximise the analytical engagement with lecturers in a hybrid blend of on-campus and remote activities.

In this paper, we report on three generations of the at-home laboratory kit developed by the author's institute and partners in the Erasmus+ project "Home Electronics

Laboratory Platform (HELP)”. The HELP kit comprises a portable signal generator and measurement instrument and a custom electronic board, which includes several functional blocks alongside the usual breadboard for assembling circuits with discrete components. The motivation for the design of each generation is introduced and the desired functionality and its implementation are described.

The impact and user experience with the kits have been assessed through student surveys and staff focus groups in the HELP consortium partners. The main themes associated with take-home electronics laboratories have also been explored in a workshop with HELP partners and contributors from other universities across Europe and the USA. This work is summarised and future potential technical and pedagogical developments are outlined.

1 INTRODUCTION

Fundamental undergraduate courses in electronics require practical experiments building and characterising circuits using laboratory equipment. This experience is crucial because it allows students to acquire essential skills such as setting up and conducting an experiment, using specialised equipment, testing, debugging, data interpretation and documentation. In our curriculum and teaching practice we seek to design our laboratory practice to achieve the 13 ABET objectives for students completing a laboratory series in an engineering undergraduate programme (Feisel and Peterson 2002) as listed in Table 1.

ABET Objectives	
Instrumentation	Creativity
Models	Psychomotor
Experiment	Safety
Data Analysis	Communication
Design	Teamwork
Learn from Failure	Ethics
Sensory Awareness	

Table 1 ABET Undergraduate Engineering Laboratories Objectives

After reviewing our traditional pre-COVID practice we determined that to achieve these objectives more laboratories should focus on providing opportunities for students to develop their own solutions, providing more design opportunities, involving formal collaborative learning and including a more explicit focus on health, safety and the environment. Laboratories that adopt enquiry, problem or project-based approaches are good candidates to improve alignment with desired outcomes such as the ABET objectives (Vesikivi et al. 2020).

The dominant approaches to laboratory practice have been in-person, simulation-based or remote laboratories. Existing research has explored ways of doing each along with their relative advantages and limitations, (Corter et al. 2011; Brinson 2015)An alternative to these three modes of delivery is the take-home laboratory which has received little attention within the engineering education research literature. A take-home laboratory (also called a distance laboratory) can be defined as an educational laboratory where students perform hands-on experiments with physical devices in their own homes.

In this article, we describe the development of take-home laboratory equipment for electronic engineering students in response to the COVID-19 pandemic. The kit has subsequently been developed to explore enhanced delivery using a blended laboratory teaching approach. Students are sent a bespoke low-cost Home Electronics Laboratory Platform (HELP) platform consisting of a combination of off-the-shelf portable test tools and a custom circuit board where students could perform typical laboratory activities. Following the success of the take-home system during COVID-19 teaching an ERASMUS+ EU project (HELP) was funded to further develop new application-driven versions of the platform. The HELP platform is open-source and so can be easily replicated within other institutions or purchased for a low cost. It can be used to enable learners to develop a rich understanding of core concepts associated with Electronic and Embedded Systems Engineering.

It can also expand access to engineering education for disadvantaged learners due to its low cost and flexible learning approach. For online and distance learning environments, low-cost take-home laboratories can increase student enrolment, help motivate learners and develop practical skills (Kennepohl 2017). This richer understanding also impacts more traditional in-person environments as take-home laboratories can be used to realise project-based experiences which have been shown to positively impact learning and enhance student retention (Vesikivi et al. 2020).

In this paper, we report on three generations of the at-home laboratory HELP kit developed by the author's institute and partners We draw on our experiences to discuss some potential applications of the current system and explore the potential for further development.

2 TAKE-HOME LABORATORY DEVELOPMENT

The traditional, on-campus, laboratory is a key element of conventional teaching and learning engineering subjects. In our programmes, 40-60% of student contact hours are allocated to application classes (lab/project). For electronics, this typically involves weekly application classes with activities focused on circuit analysis and characterisation through simulation using SPICE-based programs and by performing experiments on well-defined test setups assembled by students during the lab class. Typically, these activities require a set of standard laboratory equipment (power source, signal generator, oscilloscope, multimeter and breadboard as shown in Figure 1), and a set of electronic components, wires and connectors. This equipment is most often set up in a laboratory class with students timetabled to have 2 hours of practice time per module in the laboratory each week to carry out the required circuit experiments.

There is limited published literature on take-home laboratories with reported developments to support a variety of subject areas including mechatronics (Stark et al. 2013), fluid mechanics (Meng et al. 2018), mechanical engineering (Schajer 2021), control systems (Jouaneh, Boulmetis, and Palm 2013), embedded systems (Kommu, Uttarkar, and Kanchi 2014), digital electronics (McCarthy, Murphy, and Popovici 2022; Oliver and Haim 2009; Ruo Roch and Martina 2022) and communications (Popović et al. 2020). In the majority of these papers, the focus is on describing the kit and then describing some typical experiments to outline its use and there is little reporting of data-driven development of the kits after initial deployment.

Table 2 Progression of required circuit experiments in undergraduate electronic engineering

2.1 HELP V1.0

The HELP V1.0 kit presented in Figure 2 was developed in response to the Covid19 pandemic. It consists of a compact, standalone 3-in-1 handheld instrument - the Hantek 2D42 portable scope ("Hantek 2000 Series Product Description" 2023) - and a USB-powered electronic board, designed specifically for this purpose. The Hantek 2D42 instrument provides an Oscilloscope able to monitor two channels for frequencies up to 40MHz, an Arbitrary Waveform Generator (AWG) able to provide sine- and square-waves with programmable frequency (up to 1MHz) and amplitude (up to 2.5Vpk), as well as a Digital Multimeter.

Fig. 2. HELP kit V1.0 laboratory board and board in carry case with Hantek 2D42

2.2 HELP V1.1

The HELP V1.1 kit presented in Figure 3 was developed to address usability issues encountered with HELP V1.0 and to also add additional functionality to expand the range of experiments that students could carry out as shown in Table 2. The Hantek 2D42 was upgraded to the Hantek 2D72 as this part had more parts in stock and this provides an Oscilloscope able to monitor two channels for frequencies up to 70MHz.

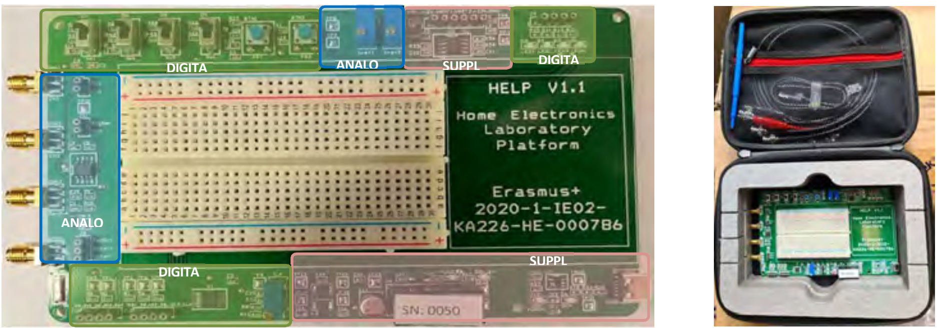

Fig. 3. HELP kit V1.1 laboratory board and board in carry case with protective foam

As with HELP V1.0, the V1.1 kit includes the breadboard, required wires and cables for all experiments, and the HELP PCB which also includes several functional blocks implemented on-board that expand the range of experiments students can perform. The main additional features are:

- symmetrical supply lines, ±12V
- power amplifier able to scale up the signal provided by the Hantek instrument, to an amplitude of maximum 10Vpk for the sinewave.
- DC voltage sources with values adjustable manually between ±10V
- digital clock generator, with frequency adjustable from 0.3Hz to 210Hz
- several switches and push buttons (both straight and debounced) to generate logic inputs and LEDs to monitor logic states.

Figure 4 presents the block diagram of the HELP V1.1 board. The functional blocks are grouped in three sections: the power supply section, the analog section and the digital section.

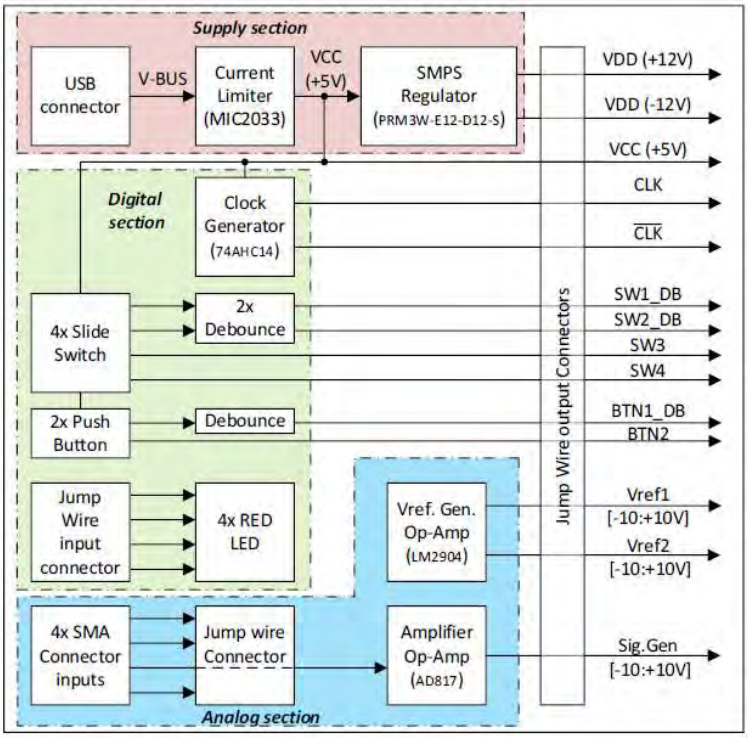

Fig. 4. Schematic of the Helpkit V1.1 electronic Board

2.3 HELP V2.0

The HELP V2.0 kit, presented in Figure 5, was primarily developed to reduce dependence on the Hantek 3-in1 instrument which was increasing in cost and restricted options for potential users. HELP V2.0 was developed to have an integrated Arbitrary Waveform Generator (AWG) able to provide sine- and square waves. The inclusion of this feature was accomplished using an Arduino Nano controlling an AD9833 Programmable Waveform Generator. The Nano board provides additional functionality expanding the range of experiments that students could carry out to include basic microcontroller programming as shown in Table 2. The kit now requires an external oscilloscope and multimeter but many institutes will have invested in such portable measuring equipment and can use the HELP kits without incurring any further cost. HELP V2.0 includes the Help Kit V1.1 electronic board functions and in addition, includes:

- Onboard Signal generator: Arduino Nano, Display, Rotary encoder
- Arduino Nano pins available for coding

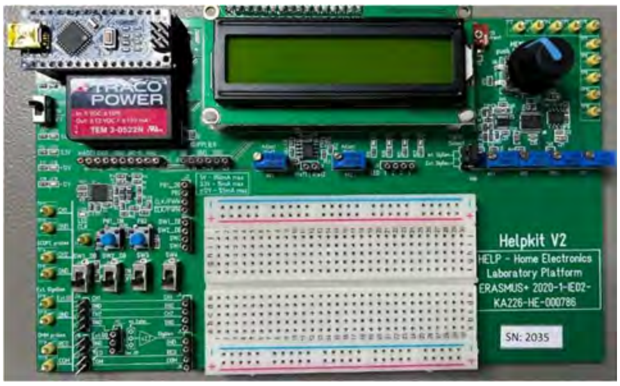

Fig. 5. HELP kit V2.0 laboratory board with the same dimensions as V1.1

The system schematic for V2.0 is shown in Fig 6. The supply section uses a different chipset with increased performance and power consumption limited to 2.5W from the 5V USB supply. The digital section has the same switch inputs and LED outputs as V1.1 but has additional ADC and PWM lines available from the Arduino Nano. The system clocks are also generated from the Arduino Nano which configures the output from the AD9833 Programmable Waveform Generator in the Analog section and amplifier gains from the generated AC signals.

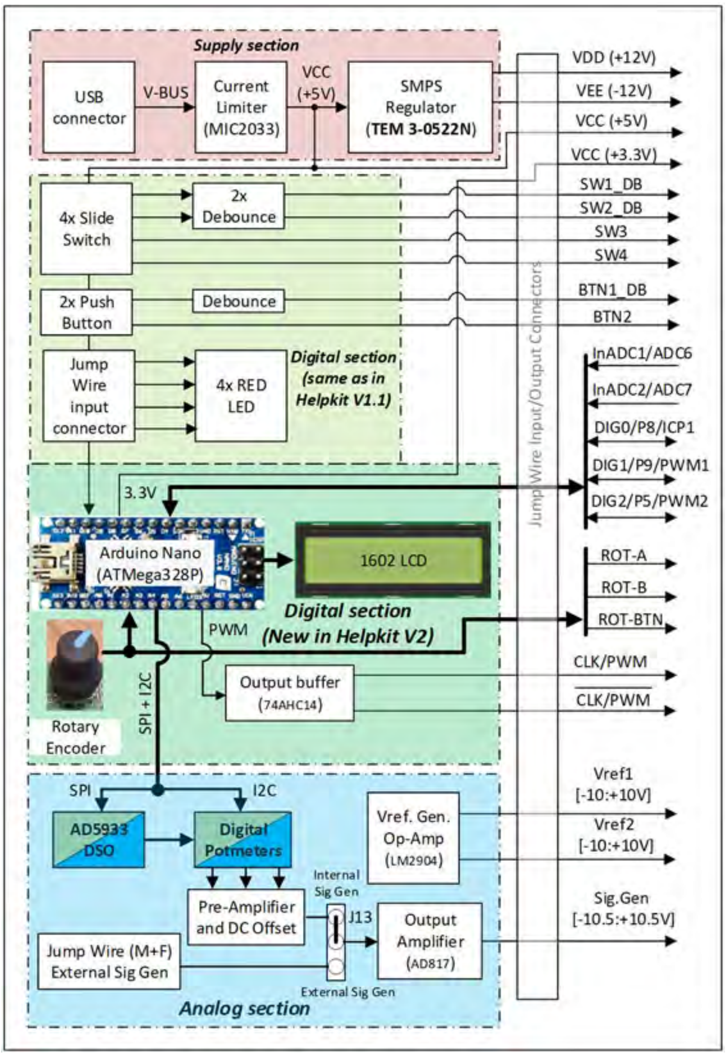

Fig. 6. Schematic of the Helpkit V2.0 electronic Board

3 RESULTS

The HELP kits have been developed and deployed over the past 6 semesters and we have tried to evaluate their impact and based on that data evolve the kit and our teaching practice to better meet the desired learning objectives for our students in laboratory sessions. In this section, we report on some of the feedback from HELP kit users and explore some possibilities for future development of the HELP kit.

3.1 Evaluation of HELP kit

The HELP kit has been used by students in several university programs at different stages of undergraduate development. Feedback on the experience of students and lecturing staff (O Mahony et al. 2022) has been gathered via surveys and focus groups. Initial feedback from learners gathered via surveys has been positive. As shown in the results of one survey presented in Fig 8, students were very positive about the lack of time constraints in completing tasks and also reported a high level of peer support in completing the experimental tasks. Relative to the on-site laboratories, the students found the more independent nature of the learning challenging and many experienced a lack of focus.

In a blended laboratory approach, the laboratory practice in pilot modules has been modified to include an increased portion of project-based activities. This involved restructuring the module activities from 100% directed exercises to a hybrid approach with 40-100% project-based activities. Modules, where students are introduced to new concepts, experimental setups, and measurements, include a higher proportion of directed learning in the early stages of the module. Student feedback has also been positive in this development.

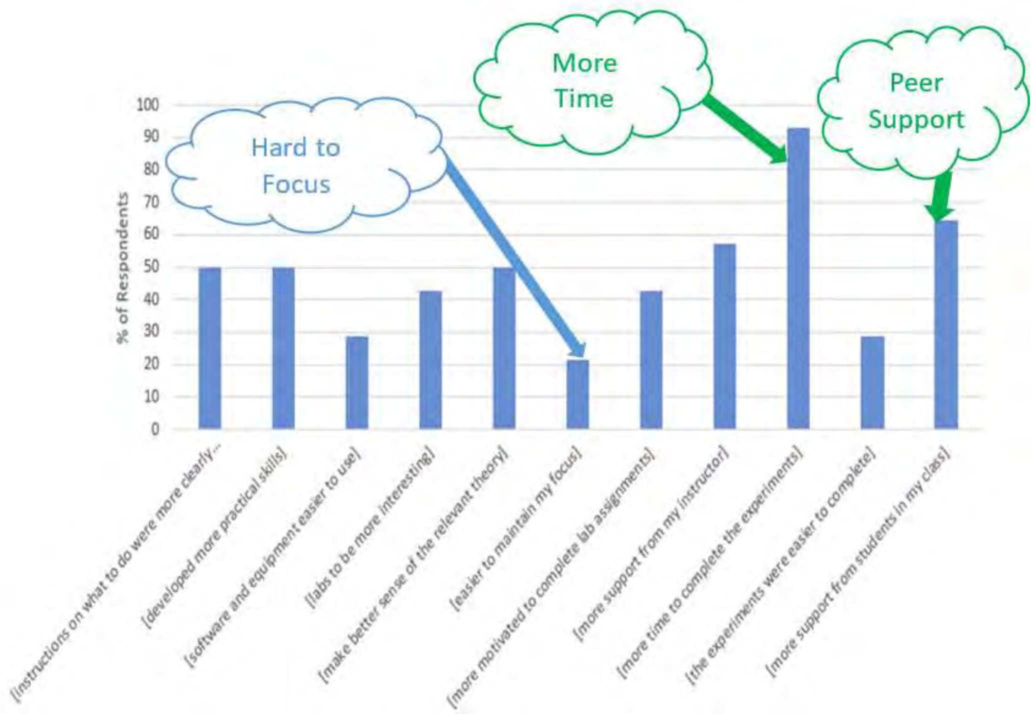

Fig. 8. Initial student feedback on HELP Take-home Laboratories

3.2 Future Development

HELP V2.0 has expanded the range of laboratory activities that can be supported with at-home delivery from our initial development as shown in Table 2. The Table also highlights those areas where undergraduate students will require additional equipment to meet their circuit design and embedded systems development laboratory needs. Future HELP developments could address the following topics:

- Cost reduction – the requirement for a two-channel oscilloscope with HELP V2.0 adds significantly to overall system cost and size for portability. The current cost for a full HELP kit is approximately €250 and this may be too costly for large scale deployment. A target cost would be to reduce this price by 50%. This could be addressed by adding a built-in oscilloscope on the HELP board with a software interface via the USB port.
- Added functionality – The kit could add FPGA and higher-power microcontrollers to the design to allow for laboratory exercises using these systems to be completed. These components could be used to develop the in-built scope function. This would make the system more complex and could reduce the simplicity of use that is attractive to students in their early years.
- Modify laboratory practice and assessment to encourage independent and collaborative activity enabled by take-home kits.
- Expand the online peer and tutor supports available to assist students and avoid excess time in troubleshooting or the associated lack of focus.

4 SUMMARY AND ACKNOWLEDGMENTS

Three generations of the at-home HELP laboratory kit which comprises a portable signal generator and measurement instrument and a custom electronic board for circuit and embedded system experimentation have been presented. The learning objectives of electronic laboratory practice have been outlined and the motivation, functionality and application level of each generation is described.

The impact and user experience with the kits has been assessed through student surveys and staff focus groups. The main benefit reported by students was increased experimentation time while the main problem encountered was in troubleshooting in the absence of tutor support. The take-home experience has been positively received by staff and students and future potential technical and pedagogical developments were outlined.

ABSTRACT

Engineers equipped with skills for a sustainable built environment have never been more critical, as government and industry sustainability goals such as the 2050 net zero target have significant implications for the construction sector. Concurrently, the UK's Construction Industry Training Board (CITB) has estimated that over 250,000 new workers will be needed by 2027 to meet demand. Besides this need for green skills, the sector is also looking towards more sustainable building materials, methods, and technologies, such as homegrown biogenic offsite manufactured (bio-OSM) timber: an innovative technology requiring additional engineering and manufacturing expertise.

To address this critical skills gap, the Timber Technology, Engineering, and Design (TED) Competency Framework was established by a coalition of academic and industry partners. This framework then informed the development of a hybrid training course that can prepare the next generation of timber engineers with the knowledge, transferable skills, and industry experience that can drive change towards sustainability in the built environment and inform a transformational approach in engineering education.

This practice paper describes the development of the Timber TED framework and the launch of the corresponding training programme in September 2022. It also reflects on the initial implementation across two cohorts, delivered at the Centre for Advanced Timber Technology at the New Model Institute for Technology and Engineering in Hereford, England, in partnership with Edinburgh Napier University and Timber Development UK. This educational initiative showcases an innovative and replicable approach to upskilling and reskilling for green skills in engineering education.

1 INTRODUCTION

80 to 90% of our time is spent in the built environment, with buildings and construction together accounting for 36% of global final energy use and 39% of energy-related carbon dioxide (CO_2) emissions (Timber Development UK 2023). With 300,000 housing starts called for by the UK government per year (UK Parliament 2022), building materials and technologies that promote sustainable and regenerative practices are essential to achieving net zero. The utilisation of modern engineered timber products like cross-laminated timber (CLT) from sustainably managed forests capture carbon and store it in the built environment resulting in an additional 1,556 to 2,567 t CO_{2e} stored in the structure of a hybrid CLT building compared to a traditional reinforced concrete building (Pierobon et al. 2019). Indeed, the embodied carbon of a house constructed using offsite panellised timber frame is approximately half that using traditional masonry forms (Monahan and Powell 2011). Timber buildings are also capable of meeting performance targets including Passivhaus Standards with high levels of airtightness and thermal and energy performance, and they can be produced efficiently using modern methods of construction that minimise waste.

However, the UK is one of the largest global net importers of timber products, creating emissions from shipping and limiting local economic growth potential from local forest resources. Of these imports, 42,500 m3 / year is of CLT. At present there is no UK commercial producer of CLT, although it has been demonstrated to be feasible (Crawford, Hairstans and Smith 2013). Scaling up the production of homegrown CLT would represent a viable way of increasing the 30% utilisation of UK produced sawn softwood in construction, estimated to be 3.6 million m3 per annum (Construction Management 2015). Besides homegrown mass timber, other advanced timber technologies can also positively impact sustainability goals by responding to the need for restoration and retrofit. Digitisation is unlocking the potential of these materials and systems, and it is also considered a game changer in the construction sector with the implementation of Building Information Modelling (BIM), the integration of Enterprise Resource Planning (ERP), the utilisation of Virtual Reality (VR) and Augmented Reality (AR), and Digital Twinning. The opportunity is a digitally connected ecosystem of built assets with a digital thread from these back to the forest floor implementing a virtual factory environment capable of improving overall productivity, maximising resource utilisation, unlocking investment and creating sustainable growth.

Yet to take advantage of these advances, the construction sector must address its skills crisis. Engineers from multiple disciplines – materials, manufacturing, civil, and structural – are needed who possess the knowledge and skills that can catalyze efforts around these opportunities for positive impact. Besides requiring more workers with new skills, the industry must change culture towards more collaborative and interdisciplinary approaches (Fort and Cerný 2022). This means new and different ways of working, requiring but also enabling flexible, hybrid learning with opportunities to engage with real world challenges, clients, and companies.

2 METHODOLOGY

The method adopted to address these needs was multistaged constructive alignment focused around three strategic actions. A constructive alignment approach was chosen because it enables a holistic educational strategy that provides a throughline between policy, learning outcomes, and pedagogy (Loughlin, Lygo-Baker and Lindberg-Sand 2020). First, a Competency Framework was developed through an iterative process of stakeholder engagement as part of a Timber Industry-approved Skills Action Plan (Timber Development UK 2023). This framework then informed learning outcome development for an educational programme mapped to those competencies. Finally, two short hybrid courses based on this programme of learning were developed for postgraduates and working professionals.

2.1 Timber TED Competency Framework

Competency frameworks are common across many industries, and they have become increasingly pertinent to sustainability education efforts; for example, EU GreenComp sets forth 12 competencies to foster a sustainability mindset through knowledge, skills, and attitudes, and the Institute of Environmental Management and Assessment articulates the sustainability skills and knowledge required at different career stages. Competency-based approaches to education have been employed since the 1960s (Nodine 2016) but have gained wider attention in engineering education in the last two decades (Henri, Johnson and Nepal 2017). Scholars have shown that these frameworks are essential for developing programmes of learning that can support future leaders and positive change within sustainability education (Lozano et al. 2017).

Professional competencies are also viewed as crucial within the UK construction sector, and the Chartered Institute of Building (CIOB) has made clear that significant up- and re-skilling in these areas is required for the 3.1 million people employed in the UK construction sector (CIOB N.d.). Indeed, in 2020, the British Standards Institution also announced the development of an overarching framework for competence in the built environment sector.

Technical competencies are essential for built environment practitioners; however the education of future engineers also requires the instillation of collaborative practices, leadership development, improved holistic understanding of the net-zero challenge, and meaningful and valuable work experience with an emphasis on SME engagement.

Against this backdrop, experts at Edinburgh Napier University, with funding from the HCI Skills Gateway, established a stakeholder group of all the main UK timber industry bodies, including the Structural Timber Association, the Confederation of Forest Industries, Swedish Wood, Truss Rafter Association, Timber Trades Federation, and Timber Research and Development Agency (the latter two now having merged to form Timber Development UK, or TDUK). These networks gave access across the interface of UK and European construction and timber sectors to consult and inform on establishing a framework with core competencies in timber relative to industry occupations and level of necessary attainment.

The development of the framework was an 18-month process which began with desk research using a range of sources, from job descriptions to existing relevant competency frameworks and chartered member requirements. Following desk research, interviews with key sector stakeholders enabled the drawing up of a first draft of the framework that was presented to working group members for discussion and feedback. Further revisions were made and additional content was developed and refined. Feedback was then obtained at two events: the Timber Engineering and Design Steering Group meeting and the Offsite/Mass Timber Construction Virtual Conference. After a subsequent review by the working group, wider views on the structure and content of the framework was sought through an industry survey.

The resulting Timber Technology Engineering and Design (TED) Framework consists of three competency areas: 1) core technical competencies; 2) cross-disciplinary competencies; and 3) core behaviours and meta skills. The competences are designed to be at English, Welsh, and Northern Irish Levels 5-7 and Scottish Levels 8-11 (equivalent to HNC/D – degree level). They assume foundation knowledge in maths, English, physics, and/or chemistry, according to job role. A depiction of the framework can be seen in Figure 1.

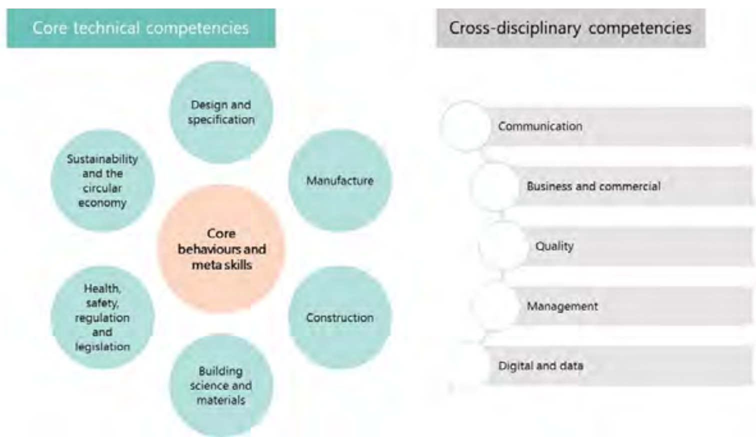

Fig. 1. Competencies Identified in the Timber TED Framework

The framework outlines specific content in each technical competency area, referring to technologies, processes, materials, systems, and standards that enable practitioners to maximise a globally responsible approach to timber construction. Six core behaviours and meta skills are identified that sit at the centre of all competency development and must be fostered alongside the technical knowledge, without which its implementation would be impeded. These are: Critical thinking and problem solving, Innovation, Collaboration and teamwork, Organisation, Professionalism and career development, and Ethics.These competencies speak to the durable, transferable skills essential to interdisciplinary and inclusive work. They spur the ability for judgement, creativity, initiative, reflection, and lifelong learning which is applicable to professional, academic, and civic life. Finally, cross-disciplinary competencies are articulated which reflect the knowledge and skills that then enable the technical competencies and core behaviours to combine for optimum capability development as well as for delivery of the sustainable built environment.

Taken together, the competencies outlined in the Timber TED Framework are designed to help learners put technical principles into practice in an effective and responsible way. Crucially, they move beyond a focus on solving technical problems and explicitly call for the development of knowledge, skills, and behaviours that reflect the broader environmental, social, and economic impacts that built environment professionals must acknowledge and grapple with. They are written so that they could easily be adapted into learning outcomes or performance standards within many engineering disciplines, meaning that they have relevance to students, educators, professionals, accreditors, and employers.

2.2 Course Development and Framework Implementation

The Centre for Advanced Timber Technology (CATT) at the New Model Institute for Technology and Engineering (NMITE) in Hereford, UK, was established in 2021 in partnership with Edinburgh Napier University (ENU) and TDUK to be a centre for timber engineering excellence and to drive the change towards new ways of building, learning, and working. In response to the development of the Timber TED Competency Framework, CATT educators developed a comprehensive and flexible training programme in partnership with TDUK. The programme is comprised of 2 hybrid short courses, TED 1 and TED 2. TED 1 focuses on learning outcomes necessary to understand timber as a structural material, the array of product options, and how they can be used to respond to a design brief sustainably. TED 2 builds on this by creating a broader understanding of timber in construction and design for manufacture and assembly approaches including available technologies. Learners gain specialist knowledge and skills for ‘better, faster and greener’ built environment delivery. Grounded in immersive ‘learning by doing’ activities, Timber TED stimulates critical thinking and instils new knowledge and skills to achieve net zero carbon. Both courses are delivered over 12 weeks and consist of three modules: a design module featuring a real-world challenge running for 12 weeks, and two complementary modules running for 6 weeks each in sequence. While the majority of learning takes place online, learners are brought together for three 3-day residential blocks where they engage with local partners, work in teams, and present their projects. To illustrate this structure, Figure 2 shows the delivery and content of the TED courses.

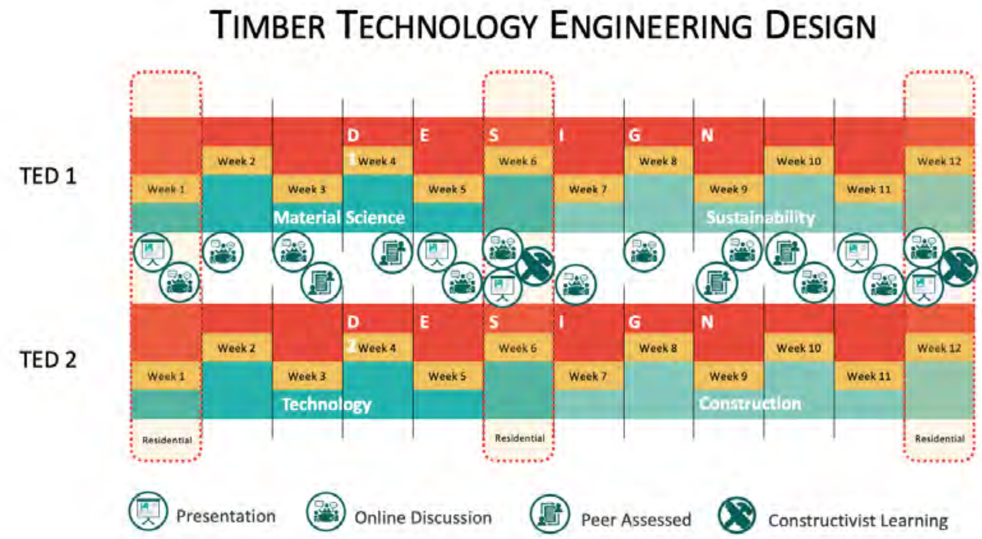

Fig 2. A visual depiction of the TED course structure

3 FINDINGS

Each strategic action has resulted in a key outcome. First, the Timber TED Competency Framework was endorsed by industry and formally released as part of a Timber in Construction Skills Action Plan in December 2022 which called for training and development in timber technical knowledge and core skills to help achieve net zero carbon. Second, the TED educational programme was approved by Chartered Institute of Architectural Technologists as a continuing professional development course, and approval is in process with the Construction Industry Training Board. Finally, the Timber TED short courses were launched at CATT in Sept 2022 in partnership with local employers Oakwrights, Taylor Lane and Border Oak as well IBI Group, Fast House and Stirling Prize Winning architectural practice dRMM and Wood Award Winner Stage One. So far, 24 learners (42% female) have undertaken TED 1 over two cohorts (September 2022 and January 2023), and the first iteration of TED 2 began in June 2023 with 11 learners participating. The learners represent many different roles and industries, including architecture, design, engineering, and sales. This allows for a multidisciplinary learning environment, enabling a more holistic approach to problem solving.

Stakeholder feedback has been collected via surveys of learners and industry partners, and it has been overwhelmingly positive. Learners particularly appreciated the experiential opportunities such as a productive forestry walk and sawmill visit, and the introduction to new skills and technologies such as timber grading and 3D scanning. Comments from the surveys include:

Quote from learner: " I believe that courses such as TED 1 offered at NMITE are required by the industry if we hope to diversify our knowledge of more sustainable construction materials and methods to reach our Net Zero 2050 ambitions."

Quote from Industry: “we need to attract into our industry the next generation, educate and train them well so that they can grow quickly into the driving force for the use of wood and all the advantages to global warming the greater use of timber brings."

These testimonials demonstrate how student demands and industry needs can collectively inform an approach to sustainable engineering for the built environment.

However, a more robust assessment approach is required to ensure alignment with the Timber TED Framework, provide guidance on continuous improvement, and inform other initiatives such as accreditation and industry recognition of professional development. Additionally, further work must be done to connect these efforts with other areas of the built environment sector. As emphasised by the report *Modernise or Die* (Farmer 2016), construction culture is broken and there is a need for improved levels of collaboration with disciplines working together to create sustainable solutions.

4 NEXT STEPS AND SUMMARY

While initial efforts have been focused on the competency framework development and the corresponding educational delivery, the next crucial component is to enact an assessment approach. This will be achieved through tools created by the Housing Construction Innovation Scotland – funded organisation Daydream Believers. In July 2023 the usefulness and transferability of their STAMP iT and STELLAR assessment tools will be employed to provide quality evaluation of the Timber TED courses and learning. A corresponding assessment activity will correlate Timber TED efforts to the CIOB Corporate Plan 2023-28 which aims to bring about cultural change that ensures quality and building safety are never sacrificed for profit and equips modern professionals with the knowledge and skills necessary to delivery construction processes in environmentally sustainable ways that also champion diversity, inclusion, and worker welfare. Further, a multi-stakeholder leadership group for timber industry skills will be established, and an open access knowledge library of timber information is being created that can be used across sectors including within engineering education. Finally, a delivery model via regional hubs across the UK is being trialed as a means for upscaling and reaching more learners.

Indeed, the innovative educational approaches adopted within the Timber TED courses (hybrid delivery, challenge-based, real-world scenarios, working in diverse teams) for the purpose of achieving the Timber Skills Action Plan could easily translate to other areas of engineering education beyond timber and beyond the built environment and serve as a model for other industries and disciplines.

Ultimately, the hope is that sustainable skills development within the built environment can in turn inform the development of more sustainable policies. When engineers are competent in the knowledge, skills, and mindsets required for responsible and regenerative design and delivery, they can develop the confidence to advocate for a better future for people and the environment.

The development of the TED1 and TED2 courses, with learning outcomes aligned to the Timber TED Competency Framework's professional skills and capabilities, demonstrate a method that could be replicated to encourage innovative engineering education that meets the need for sustainable engineering practice.

ABSTRACT

In addition to the technical content, modern courses at university should also teach professional skills to enhance the competencies of students towards their future work. The competency driven approach including technical as well as professional skills makes it necessary to find a suitable way for the integration into the corresponding module in a scalable and flexible manner. Agile development, for example, is essential for the development of modern systems and applications and makes use of dedicated professional skills of the team members, like structured group dynamics and communication, to enable the fast and reliable development. This paper presents an easy to integrate and flexible approach to integrate Scrum, an agile development method, into the lab of an existing module. Due to the different role models of Scrum the students have an individual learning success, gain valuable insight into modern system development and strengthen their communication and organization skills. The approach is implemented and evaluated in the module Vehicle Systems, but it can be transferred easily to other technical courses as well. The evaluation of the implementation considers feedback of all stakeholders, students, supervisor and lecturers, and monitors the observations during project lifetime.

1 INTRODUCTION

Including practical training of professional skills into existing modules is rather challenging and many different teaching strategies were developed with different emphasis on problem or project based learning, online and offline activities or active learning (Fitzgerald and Lentmaier 2016, Aluvalu et al. 2017). Problem or project-based learning (both abbreviated with PBL) or cooperative learning are commonly used methods to combine technical and non-technical content (Fedorinova et al. 2018, Prasad and Reddy 2015, Fernandez 2017, Johnson and Hayes 2016). Problem based learning approaches define a specific problem to be solved by the students, whereas project-based learning relies more on self-defined projects of the students. These methods target to motivate the students to be engaged with the material, show interest in the course contents, participate in the class and collaborate with other students. With regard to electrical engineering, PBL is commonly used, both for complete curricula like in (Macías-Guarasa et al. 2016) or for dedicated courses (Kumar et al. 2016). Many projects at university have a dedicated deadline and the time between start of the project and the deadline is often managed spontaneously by the student team. As most students have no experience in project management, sometimes just a few team members do all the work without any overall structure. Therefore, a dedicated project development method should be implemented.

Agile development focuses on flexibility, collaboration and self-organisation to increase the efficiency of a team during an iterative development process (Dyba and Dingsoyr 2009). The success of this methods relies strongly on dedicated professional skills of all team members, including team work, expedient communication and feedback, engagement and reliability. Acceptance of this method including all the required skills and tools for collaboration is essential for all team members. Hence, incorporation of agile development as dedicated PBL into university courses directly enables the students to improve their professional, communication and social skills and to train modern development processes, which make the students feel more confident in working together and also discussing problems.

1.1 Module Vehicle Systems

The course Vehicle Systems is part of the curriculum of the bachelor program Electrical Engineering at UAS Aachen (FH Aachen 2023). It covers different kind of systems in modern vehicles, from powertrain systems to advanced driver assistance systems (ADAS) and autonomous driving. The course consists of lecture (2 lessons per week), exercise and lab with 1 lesson per week, respectively. Up to 50 students participate in this one-term-course of 14 weeks every year. The previous knowledge of the students is rather heterogeneous as some students already finished a vocational training in the area of vehicle mechatronics or similar.

The goals of the course are rather simple: every student should gain competencies in technical fields and applications of vehicle systems as well as professional skills needed for modern development methods like agile development.

A flipped classroom concept was introduced for the module in the last years. During the lab, the students used a vehicle dynamics simulation software, IPG carmaker, to develop an adaptive cruise control system for a car (ACC). So far, all steps were predefined in the lab manual, from the initial setup and start-up of the software to the different development steps to realize the final system. In addition, an agile development method, Scrum, was introduced to increase professional skills of the students. The following description focuses on this introduction of agile development into the lab.

1.2 Agile development

Agile development is an established process for the iterative software development (Zhong et al. 2011). Its key element is a feedback loop which offers a continuous improvement not only of the product, but as well of the collaboration of the development team and the clients. The Agile Manifest defines four guiding principles (Cohn 2010). Individual strength and weaknesses of team members should be concerned and used so that the whole team learns interdisciplinary. The final product can only be achieved by reacting on changes during the implementing process, like changes of features of the productor financial, timing or personnel changes. This is a contrast to the normal development approach which focusses on fixed processes and working instruments, comprehensive documentation, a contract and plan agreed with the customer.

Goals of agile development are a higher motivation, engagement and productivity, as well as continuous working, iterative learning, a project structure by defining responsibilities and at the end a faster way to the final product state.

A common agile project method framework is Scrum. Here, three main roles define the Scrum team, which are the Scrum Master, the Product Owner and the development team (Gloger 2016). A sprint is a processing time interval for implementing a version or part of the product, the product increment. The sprints are supposed to have mostly the same length to maintain a continuity in working and planning, so time scheduling becomes easier. The product backlog defines a red line of tasks and is dynamic, in contrast to a linear project. The new prioritisation for the next sprint is continuously adjusted during the current iteration. At the end of a sprint the highest prioritised tasks are set to the sprint backlog to get implemented. The Product Owner is responsible for this procedure. At this point the Scrum Master has to accomplish the Sprint Review, Retrospective and Sprint Planning to organise a new working iteration and especially turning the focus on reflecting the previous collaboration. During the iteration the Scrum Master also organises Daily Scrums. This helps the whole team to get an overview of the project state and the responsibilities. Furthermore, the Scrum Master should identify possible collaboration problems in the Scrum team and help the team solving them.

2 METHODOLOGY

2.1 Concept and implementation

In 2022, 33 students participated in the course lasting for 14 weeks. The lab using Scrum for the ADAS development is based on the previously used lab. The initial structure of the lab is not change from technical point of view, incl. the dedicated tasks that are covered by the lab manual to develop an ACC system. This structure is maintained to ensure that all students are able to complete the tasks and to gain the required technical skills. The development of an emergency brake assist system (EBA) is added to the lab without dedicated tasks to enable a free and flexible work for the students. For both parts of the lab, the predefined and the free part, Scrum was used.

Depending on the group size the time effort and effort per person can be estimated as seen in Fig. 1. The time effort is most efficient with 5-7 people. The productivity per person is also better in smaller groups, but it does not vary that much between 1-7 people (Cohn 2010). For this project, productivity was defined as degree of achievement of the required professional skills and technical knowledge and a positive development within the process. Effort is referred to the time spent on the project. Referring to this statistical observation, six to seven students formed a Scrum team.

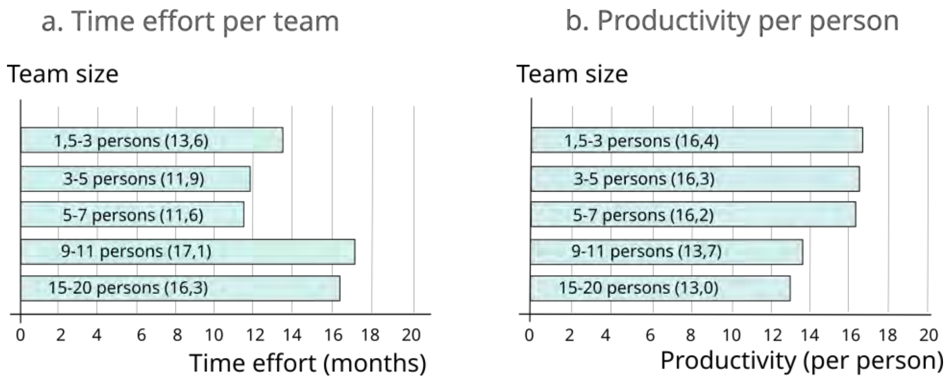

Fig. 1: Evaluation of team size acc. to (Cohn 2010)

The students self-selected their group at the beginning and hence, the groups differed in the composition of the team members. For some groups the team members already knew each other (group type 1), for other groups the team members did not know each other before (group type 2).

In general, the Scrum Master and the Product Owner should not be part of the development team to avoid personal conflicts (Cohn 2010). Nevertheless, all students should reach the technical goals of the course. Hence, for this project the Product Owner and the Scrum Master also act as team members to be able to follow the technical implementation completely.

Weekly Scrum meetings with supervision by a lecturer were held by each group. As it was impossible to implement a Daily Scrum event, every team accomplished at least one further meeting per week without supervision.

The supervision meetings started with the sprint review, where the product increment was presented, as well as the technical state of each team member. Afterwards the

Scrum Master moderated the retrospective. Positive feedback and observations of the last sprint, as well as problems were communicated, followed by discussions about improvements. The last step was the sprint planning to prioritize the next tasks of the product backlog, to estimate the effort and to assign the responsibilities.

The Product Owner communicated all technical requirements with the lecturers as needed. Another important task of the Product Owner was to update the Product Backlog and to ensure that the technical objective is achieved and that the quality requirements of the functions in IPG Carmaker were also observed.

To get an overview of the tasks and their current state as well as to update the tasks continuously, the online tool Trello was used (Trello 2023). The Trello boards were designed individually by the teams reflecting the four categories 'Stories/Product Backlog', 'Tasks/Sprint Backlog', 'Work in Progress' and 'Done'. To maintain the goal of technical learning success for all students, the 'Definition of Done' (Gloger 2016) in this project was that each team member implemented and understood the tasks.

At the beginning of the project a few moderation tips were given, but afterwards the students should first try to find their own way of moderating. During the supervised meetings recommendations were given when needed, e.g. how to handle a situation or how to structure a meeting. In the end, each group presented their organisational process and the technical results.

3 RESULTS

3.1 Evaluation

The evaluation of the implemented Scrum method is done in different steps, analysis of different aspects over project lifetime, observations of the lecturers, statements from the students and the official evaluation of the module.

Analysis of different aspects

Three different aspects – Scrum elements, group behaviour and results – with corresponding sub-items are analysed as depicted in Table 1. The analysis of the group behaviour was based on three sub-items reflecting the acceptance of the process by the Scrum Master and the group and the observation of active participation during the meetings. For the results, the communication within the group, the achievements during the project work and the retrospective were analysed. The numbers 'x/y' indicate the result of the analysis for each group at the beginning and the end of the project, respectively. As indicated by light green and green, the results improve significantly over project lifetime for most of the items and groups. In the end, all items but 3 achieve a very good result of 7 and more. Just for two groups the tool (Trello) is judged worse at the end of the project.

Observations by lecturers

As the two lecturers acted as supervisors during the weekly Scrum meetings, they are able to observe the group behaviour, the different roles and the communication very closely. Some observations show a clear difference between the two different group types, some observations were very much the same for both group types.

For all groups the direct communication improved during the project, in particular for groups of type 2. The initial meetings of these groups were rather silent, but after some time an active communication took place, strongly motivated by the corresponding Scrum Masters. Some groups established additional communication via a messenger for asynchronous communication between the meetings. This kind of communication did not work well, as questions were often answered too late from other team members, blocking the questioner with this task. The issue was solved in the Retrospective by forming sub-groups of two people. Other groups solved a similar problem with an additional online or presence meeting with the whole group.

Table 1. Analysis of different aspects of the implemented Scrum method on a scale from 0 (worst) to 10 (best). Numbers indicate the value at the beginning and at the end of the project. Yellow: slight deterioration, light green: slight improvement, green: strong improvement

	Scrum elements			Group behaviour			Results		
Group	Tool (Trello)	Roles	Procedure	Acceptance by group	Acceptance by Scrum Master	Active participation in meetings	Communication	Achievements	Retrospective
1	8/7	7/9	6/10	8/10	8/9	8/10	8/10	10/10	6/9
2	3/7	3/9	3/9	8/10	10/10	4/8	6/8	5/8	4/7
3	7/6	8/8	6/9	7/8	7/8	6/8	9/9	9/10	6/7
4	6/10	6/8	7/8	5/7	6/7	6/7	5/6	9/10	4/6
5	6/9	4/9	5/10	6/9	8/10	5/9	3/7	4/7	6/9

Initially, all Scrum Masters had to find their role as a moderator and they had to learn that their task is not to find the perfect solution by themselves. Over time, all Scrum Masters managed to moderate their group and the meetings properly, the moderation style and extent strongly depended on the group type. For group type 2 the moderation efforts were significantly higher. It was remarkable that the Scrum Masters learned to change their role from team member to Scrum Master and back easily.

For all groups there was a steep learning curve regarding the Scrum process. In the beginning, the technical status update, the retrospective and the sprint planning were not properly separated but were mixed up altogether. With some support of the supervisor all groups found a better meeting structure reflecting the Scrum process with separated sections for the update, retrospective and sprint planning. Groups of type 1 did not follow the process too close but sometimes started side discussions during the meetings. These discussions were stopped after some time by the Scrum Master. In general, groups of type 2 oriented themselves more exact on the Scrum rules compared to groups of type 1 reflecting the need for a clear structure to support the communication of the type 2 participants. Overall, the atmosphere in the groups was very harmonic and result-oriented.

The role of the Product Owner did not have a high significance in this specific project due to the missing customer and missing change requests. Anyway, the Product Owners supported the Scrum Masters and communicated technical questions with the lecturing professor. For the dynamic aspects of the project, in particular during the sprint planning with corresponding task prioritization, Trello as a taskboard was of great benefit for all groups. Open and new task cards were replanned according to their new prioritization and relevance. Due to missing experience with the tasks and the corresponding effort, sometimes not all tasks could be completed as planned, and sometimes the tasks were finalized long before the end of the sprint. In the latter case, the group reflected that they should have distributed the previous tasks better over time and iterations. All in all, the dynamic structure allowed the students to manage their time individually and to react on problematic tasks.

Direct feedback of students

After the course finished, the students were asked for direct feedback in form of a question-leaded discussion in plenum with all students and additionally of a group-internal reflection. All in all, the project work was considered to be very good and helpful for their future work, in particular the structure and the Scrum roles. The Scrum method was appreciated in general, but for some students the effort for implementing and living Scrum was too high. These students preferred to have more time to work on the technical topics. Trello gave a good overview of the status of the project and each team member. Also, the individual goals defined in each sprint were helpful to work continuously. All groups profited from the organizational skills and the efforts of the Scrum Master. Hence, as the Scrum Master acted also as developer, the effort for the Scrum Master was higher than for other team members. During the time the effort for the Scrum Master decreased as the meeting procedure was more clear. The role of the Product Owner was unclear in this context and the students proposed to include the role of a customer. Face-to-face meetings were preferred to online meetings and were usually more productive. Regarding the technical tasks, the students concluded that Scrum was more helpful for the free EBA task, including higher creativity, better teamwork and communication and increased use of Trello.

Module evaluation

The module was also evaluated with a standard questionnaire that is used for all modules, just about half of the participating students participated in the questionnaire. Some students judged the method to be ineffective and too time-consuming, especially for the first, conducted part of ACC development. However, it was considered more helpful for the EBA task. Others found it interesting and helpful for structure and teamwork.

3.2 Discussion

The purpose for implementing an agile development process was to increase the professional skills of the students and to introduce Scrum as a state-of-the-art tool. Professional skills like communication, role behaviour and process understanding were strengthened for all participants due to the interactive meetings and the agile project structure. Just little effort was spent by the supervisors in the beginning to introduce the process, to guide the initial meetings and to give some hints for improvement. The extra effort for the students was judged to be not too high, even though not all students liked this way of project work in the lab. In contrast, most students appreciated the learning outcome and agreed with the extra effort.

The effort for the Scrum Master, when also acting as developer, is higher compared to the other team members. On the other hand, Scrum Master benefits by increased management and organizational skills. Changing the Scrum Master during the project could spread this learning outcome also to other students, but at the expense of more unstructured project setup. This idea could be tested in following labs.

Due to missing customer or external change requests, the role of the Product Owner was not really useful in the current setup. In the next turn, either a customer request or change requests can be introduced by the lecturers to increase the work for the Product Owner.

The Scrum method fitted very well to the free part of the lab, the development of EBA. Here, all advantages and features of agile development were clearly visible for the students. Some groups worked in sub-groups with two students implementing different solutions for the tasks. During the following Sprint meeting advantages and disadvantages of the different solutions were discussed and the best fitting solution was selected, improving the project outcome.

For the conducted part of ACC development, Scrum did not fit that good due to missing dynamics of the project. But, based on this approach, Scrum was introduced rather softly, and the students could focus on the technical aspects first. Nevertheless, for future labs it could be tested to run the static part of the project (ACC) in a conventional way without Scrum, and to use Scrum just for the dynamic second part (EBA).

The final technical results of all groups were very good and very similar to former years. All groups managed to run the static part of the lab, and for the EBA development they found different, but always working solutions. Therefore, all technical learning goals were fully reached.

As Scrum is a general agile project management method, it can easily be transferred to other modules. According to the results of the implementation presented in this paper, the lab should contain at least some free parts. For these free parts Scrum could provide many benefits to increase the professional skills of the students, introduce and experience a modern development process maintaining the technical learning goals. The roles and the concrete implementation of the process can be adjusted to the modules easily as well.

4 SUMMARY AND ACKNOWLEDGMENTS

The introduction of Scrum as an agile development method into an existing lab of the module Vehicle Systems is presented. The purpose is to increase the learning outcome with regard to professional skills, maintaining the technical learning outcome. The lab consists of a conducted part and a free part, and Scrum is applied for both. The benefits of Scrum are higher for the free part of the lab reflecting the dynamic development of this part. In general, the effort to implement and lead the Scrum process is medium, whereas the extra efforts for the students is rather low. Nevertheless, the benefits for the students with regard to professional skills and process understanding is significant.

ABSTRACT

Given the increasing criticality and complexity of societal challenges, higher education institutions are urged to equip students with the ability to develop sustainable solutions for 'wicked' problems. Consequently, the Challenge-based Learning (CBL) framework has attracted considerable interest in higher engineering education. However, transforming existing course curricula to CBL is a challenging endeavour since it requires careful and paced execution for maintaining the quality, synergy, and flow of existing education. Therefore, this paper proposes a perspective on CBL implementation that exemplifies a gradual transition towards educational CBL innovation while reflecting on the alignment, consistency, and coherence educators aspire to when designing courses. Accordingly, we introduce a CBL implementation continuum as a conceptual model, which connects CBL elements to Van den Akker’s Spider Web for curriculum design and describes a continuum of Mild, Moderate, and

Intense CBL levels per Spider Web component. Moreover, the paper describes an online CBL implementation tool, which helps educators thoughtfully evaluate the current level of CBL in their courses and provides practical recommendations for a transition towards higher levels of CBL intensity.

1 INTRODUCTION

In this ever-changing world, humanity is confronted with inherently intricate, critical, and ever-evolving problems. Consider, for example, the issues of climate change, energy transition, pandemics, and social injustice. These so-called “wicked” problems require innovative approaches and competencies that transcend current methods of problem-solving. Consequently, higher education institutions are urged to equip students with the ability to develop sustainable solutions for wicked problems, in addition to teaching academic knowledge and soft skills.

As a result, Challenge-based Learning (CBL) has attracted substantial interest in higher education. In CBL, students, as well as teachers, field experts, and community members collaborate to actively address wicked problems relevant to their environment while acquiring deep content knowledge and advanced soft skills (Apple Inc. 2011; Nichols et al. 2016; Rodríguez-Chueca et al. 2019).

Key CBL elements are widely described in practical handbooks and scientific literature. This literature often outlines flexible learning paths, inter-/trans-disciplinarity, real-world impact, 21st-century skills, self-directed and inquiry-based learning, flexible teacher roles, stakeholder involvement, and flexible assessment as elements of CBL (Apple Inc. 2011; Nichols et al. 2016; Gallagher and Savage 2020).

Designing education, especially while embracing these CBL elements, is a wicked problem in itself. Practice shows that the transition to CBL can be difficult and requires careful execution since the rushed application of CBL in a course (re-)design can disrupt the balance of (ongoing) education.

To support teachers and educational designers in moving from established practices in higher education to the creation of fully realised CBL courses, we propose a conceptual model, the CBL Implementation Continuum, that exemplifies a gradual transition towards educational CBL innovation while reflecting on the alignment, consistency, and coherence that educators aspire to when designing courses. To create this model, first, we connected CBL elements to Van den Akker’s Curricular Spider Web components (Van den Akker 2003), reflecting the alignment, consistency, and coherence desired in a curriculum. Then, we developed a continuum of varying CBL intensity, defining Mild, Moderate, and Intense CBL levels per component of the Spider Web. In addition, we introduce an online tool that supports the implementation of CBL in course design based on the Implementation Continuum.

2 CONNECTING CBL ELEMENTS TO THE SPIDER WEB COMPONENTS

To connect CBL elements to Van den Akker's Spider Web, we started by summarising key CBL characteristics found in the relevant literature and identifying how these align with each Spider Web component. Next, to grasp how CBL implementation can vary in course designs, we examined the implementation of CBL at the University of Twente through three cases: a bachelor-level minor (C1), a master-level extracurricular module (C2), and a master-level curricular course (C3).

As a result, we propose a Mild-Moderate-Intense Continuum per Spider Web component. At the Mild level, we guide incorporating CBL essentials into existing educational structures. The Moderate CBL level builds on this, introducing more CBL elements into the curriculum and adding depth to the CBL experience. At the Intense level, we describe a full-scale implementation of CBL, where all elements are fully integrated into the course design.

The formation of the continuum definitions of the components of *learning rationale*, *grouping*, and *assessment* are illustrated as an exemplar within this article, reflecting the underlying reasoning behind the model.

2.1 CBL Learning Rationale

In Van den Akker's Spider Web framework, the *learning rationale* describes why students learn in a curriculum. In CBL, students learn to interact and have an impact on the real world (Apple Inc. 2011; Nichols et al. 2016). They are presented with a big idea, a wicked societal problem, which needs to be broad enough for students to define and choose actionable challenges that require a solution design (Apple Inc. 2011; Nichols et al. 2016).

To incorporate CBL into their course, teachers can start by introducing a big idea that encompasses a wicked societal problem. The big idea should empower students to define their own actionable challenges and design solutions while engaging with real-world communities and stakeholders. In the meantime, real-world impact within a curriculum can manifest in various ways. In Mild CBL courses, student impact is limited to providing recommendations for a challenge solution, while the implementation and evaluation of the solutions are left to others. In such a way, Mild CBL courses allow students to have a passive impact on the real world.

To elevate the implementation of CBL to a Moderate level, teachers can guide students in prototyping solutions and fostering a more active impact on the real world. Additionally, the literature emphasises the value of guiding students to personally connect with the big idea, as it increases the perceived sense of meaning (Apple Inc. 2011; Nichols et al. 2016). Thus, in Moderate CBL courses, teachers scaffold students in defining challenges that have personal relevance to them.

Lastly, a full-scale CBL experience empowers students to leverage their learning process for societal contribution and witness their influence on real-world communities. As a result, students are required to design and implement solutions that have an immediate impact on the chosen challenge and evaluate the effects of their solutions in real life (Apple Inc. 2011; Nichols et al. 2016).

In summary, the Mild CBL level, within the learning rationale, is characterised by interaction with the real world, passive impact, broad big ideas, wicked problems, actionable challenges of personal choice, and solution designs. The Moderate CBL level introduces the characteristics of active impact on the real world and challenges of profound personal relevance. Lastly, Intense CBL courses, in addition to the Mild and Moderate level descriptions, provide students with opportunities to have an immediate impact on the real world. See Figure 1 for a visual overview.

Applying these CBL levels to the learning rationale of the aforementioned cases, C2 and C3 were categorised as Mild CBL, while C1 was Moderate CBL. In both C2 and C3, students chose actionable challenges from a broad big idea presented by field stakeholders, but the big idea was confined to a specific case, limiting personal exploration. The solution design resulted in an advice report, creating a passive impact. Conversely, C1 offered a pool of big ideas for students to select from, facilitating the choice of a personally relevant challenge. C1 also enabled students to design prototype solutions and evaluate their effectiveness with primary stakeholders, creating a more active impact. If teachers of C1 would want to promote their CBL implementation to the Intense CBL level, they would scaffold the students in applying their solution designs in real-world settings and evaluate their effectiveness with a broader range of stakeholders.

2.2 CBL Grouping

The Spider Web's *grouping* component depicts with whom students are learning. When applied to CBL, literature accentuates the significance of fostering inter- or trans-disciplinary collaboration within a group for a deeper understanding of the big idea (Observatory of Educational Innovation 2015; Nichols et al. 2016; Gallagher and Savage 2020; Dieck-Assad et al. 2021). Consequently, Mild CBL level courses can start by enabling students of the same discipline to work together while looking at the challenge from diverse perspectives to ensure a rich and critical exchange of ideas.

To take CBL a step further, teachers can facilitate forming groups of students from various disciplines to foster a multidisciplinary perspective on the challenge (Nichols et al. 2016; Gallagher and Savage 2020; Dieck-Assad et al. 2021).

Finally, Intense CBL groups consist of students, *and* coaches (i.e., teachers), *and* stakeholders. In such a way, coaches and stakeholders enrich their team's understanding of the big idea and the real-world context while students provide original perspectives on the addressed topics. Ultimately, the group members become active co-learners, co-researchers, and co-designers (Baloian et al. 2006; Nichols et al. 2016; Chanin et al. 2018).

Accordingly, regarding the grouping component, Mild CBL courses enable students within the same discipline to collaborate and explore the chosen challenge from diverse perspectives. Moderate CBL courses encourage the formation of groups with students from various disciplines to foster a multidisciplinary perspective. The Intense CBL level requires forming groups of students, coaches, and stakeholders who actively collaborate as co-learners, co-researchers, and co-designers.

The three analysed cases were characterised by different levels of CBL on the grouping component. C3 had a Mild level of CBL, with students from the same discipline encouraged to collaborate interdisciplinarily. The students were expected to explore their challenges from diverse perspectives and leverage their personal experiences during the investigation. C2 was considered to have a Moderate-to-Intense level of CBL, as students formed multidisciplinary groups and were required to collaborate transdisciplinary, with occasional participation from primary stakeholders and teachers during team reflections. C1 had an Intense level of CBL, with multidisciplinary groups and active participation from the team coach and primary stakeholders throughout the process.

2.3 CBL Assessment

In CBL, assessment focuses on the learning process rather than the final product (Nichols et al. 2016). Mild CBL level courses can start by assessing both the learning process and the challenge solution. The assessment of the learning process can be restricted to an overall reflection on the progress made throughout the CBL experience. As for the learning product, CBL assessment usually draws attention to the feasibility of the solution design (Apple Inc. 2011; Nichols et al. 2016; Yang et al. 2018; Gallagher and Savage, 2020). Hence, similarly to the common assessment of projects, teachers and/or stakeholders of Mild CBL courses define assessment criteria focusing on utilising course content into solution designs and their feasibility.

Moderate CBL courses build on this by emphasising creativity and innovativeness of the solution design within the assessment criteria (Yang et al. 2018; Gallagher and Savage, 2020). Moreover, Moderate CBL courses incorporate critical reflections on the successes and failures of the learning process, as these are valuable for a CBL experience (Apple Inc. 2011; Nichols et al. 2016; Yang et al. 2018). Lastly, the literature introduces the role of a student as a co-assessor of the learning process (Nichols et al. 2016; Cruger 2017). Therefore, Moderate CBL courses allow student contribution to the assessment. Practically, it often manifests in students critically evaluating their progress.

Intense CBL courses take the evaluation of the learning process to the next level. Students and teachers become co-assessors of the learning process, choosing the assessment procedures and criteria (Nichols et al. 2016; Cruger 2017). They define the assessment criteria, which usually includes the assessment of students' achievement of personal learning objectives, decision-making, reflection on the successes and failures of the learning process as well as reflection on the solution design's creativity, innovation, and feasibility (Nichols et al. 2016; Yang et al. 2018).

Thus, Mild CBL courses assess both the learning process and the challenge solution, focusing on the effective utilisation of course content and solution feasibility. Moderate CBL courses incorporate creativity, innovation, and critical reflections on the learning process, allowing student contribution to the assessment. Intense CBL courses involve students and teachers as co-assessors, defining assessment criteria that encompass personal learning objectives, decision-making, reflection on the learning process, and evaluation of the solution design's creativity, innovation, and feasibility.

Accordingly, C2 was aligned with the Mild CBL level descriptors. C2 teachers evaluated both the learning product and the process, focusing on how students applied their knowledge and skills to their solution designs, the feasibility of the solution, and their overall reflection on the learning experience. C3 had a Mild-to-Moderate level of CBL, guiding students to reflect on process successes and failures as part of the assessment. C1 had Moderate CBL level elements, assessing the creativity and innovativeness of students' solution designs and prioritising reflections on the learning process. Assessment criteria in C1 focused on students' ability to justify their choices, evaluate their progress, and critically reflect on process successes and failures. Bringing the curricular design to the Intense CBL level in C1 would involve students defining the assessment procedures and criteria alongside teachers and stakeholders.

2.4 CBL Implementation Continuum

Accordingly, Figure 1 presents the CBL Implementation Continuum in full:

Learning Rationale: why are students learning?

Mild CBL:

- Interaction with the real world
- Passive impact on the real world
- Broad big ideas
- Wicked problems
- Actionable challenges
- Challenges of personal choice
- Solution design

Moderate CBL:

- Interaction with the real world
- ***Active impact*** on the real world
- Broad big ideas
- Wicked problems
- Actionable challenges
- Challenges of personal choice
- Challenges of ***profound personal relevance***
- Solution design

Intense CBL:

- Interaction with the real world
- Active ***and immediate impact*** on the real world
- Broad big ideas
- Wicked problems
- Actionable challenges
- Challenges of personal choice
- Challenges of profound personal relevance
- Solution design

Learning Objectives (LOs): towards which goals are the students learning?

Mild CBL:

- Reflection on existing knowledge and skills is facilitated
- Students mainly work towards pre-defined specific learning objectives

Moderate CBL:

- Reflection on existing knowledge and skills is facilitated
- A pool of ***pre-defined broad LOs*** (incl. academic and 21st-century skills) is presented
- Students are independent in ***choosing LOs from the pool***

Intense CBL:

- Reflection on existing knowledge and skills is facilitated
- Students are ***independent in defining personal LOs***
- Academic knowledge and 21st-century skills are ***encouraged***

Content Knowledge (CK): what are the students learning?

Mild CBL:

- Groups of students together gain inter-/trans-disciplinary knowledge (content and soft skills)
- The scope of CK is mainly defined by the course
- The scope of CK is partially defined by students' challenge investigation needs

Moderate CBL:

- Groups of students together gain inter-/trans-disciplinary knowledge (content and soft skills)
- The scope of CK is ***partially*** defined by the course
- The scope of CK is ***partially*** defined by students' challenge investigation needs

Intense CBL:

- Students ***independently gather disciplinary knowledge*** (content and soft skills)
- A group of students ***combine*** their disciplinary knowledge and ***build*** an inter-/trans-disciplinary ***knowledge base***
- The scope of CK is ***entirely*** defined by students' challenge investigation needs

Learning Activities: how are the students learning?

Mild CBL:

- Interaction with the real world
- Passive impact on the real world
- Broad big ideas
- Wicked problems
- Actionable challenges
- Challenges of personal choice
- Solution design

Moderate CBL:

- Students (individuals or groups) engage with a wicked problem (i.e., big idea)
- They identify an actionable challenge
- They deeply investigate the challenge
- They ***independently engage with the primary stakeholder***
- They design a consciously chosen solution
- They (indirectly/directly) implement the solution in the real world
- They ***evaluate the effects*** of the solution
- A ***cycle*** of ***reflecting*** and ***documenting*** follows the process

Intense CBL:

- ***Individual students engage*** with a wicked problem (i.e., big idea)
- ***Individual students identify immediate*** actionable challenges
- Students ***form groups*** based on their actionable challenge
- The group deeply investigates the challenge
- The group engages with ***any relevant stakeholder*** independently
- The group designs a consciously chosen solution
- The group ***directly*** implements the solution in the real world
- The group evaluates the effects of the solution
- A cycle of ***reflecting, documenting, and sharing*** with the public follows the process

Teacher Role: how is the teacher facilitating the students' learning?

Mild CBL:	Moderate CBL:	Intense CBL:
• A learning supervisor (expectation manager, process facilitator) • Field experts and professional advisers	• A learning supervisor (expectation manager, process facilitator) • A ***coach*** (a ***learning guide***) • Field experts and professional advisers	• A learning supervisor (expectation manager, process facilitator) • A coach (a learning guide, ***co-researcher/co-designer/co-learner***) • Field experts and professional advisers

Materials & Resources: with what are the students learning?

Mild CBL:	Moderate CBL:	Intense CBL:
• Teachers prepare guiding resources • Students must familiarise themselves with the guiding resources • Students are encouraged to explore additional resources • Technology can be used	• Teachers prepare guiding resources • Students ***can choose to*** familiarise themselves with the guiding resources • Students are encouraged to explore additional resources • ***Open access to technology is provided***	• Teachers prepare guiding resources • Students can choose to familiarise themselves with the guiding resources • Students are encouraged to explore additional resources • Open access to ***state-of-the-art technology*** *is provided*

Grouping: with whom are the students learning?

Mild CBL:	Moderate CBL:	Intense CBL:
• Students form a group of co-learners • Inter-/trans-disciplinary collaboration is fostered	• Students form a ***multidisciplinary group*** of co-learners • Inter-/trans-disciplinary collaboration is fostered	• A multidisciplinary group of ***co-learners*** consists of: – ***students*** from different disciplines – ***coaches*** (teachers) – ***stakeholders*** • Inter-/trans-disciplinary collaboration is fostered

Location & Time: where and when are the students learning?

Mild CBL:	Moderate CBL:	Intense CBL:
• Fixed learning in the real world • Fixed L&T for the offered learning activities • Flexible L&T for self-regulated learning and group work • A collaborative virtual and/or physical workspace is accessible by schedule	• ***Semi-fixed*** learning in the real world • ***Semi-fixed*** L&T for the offered ***learning activities*** • Flexible L&T for self-regulated learning and group work • A collaborative virtual and/or physical workspace is accessible by schedule	• ***Flexible*** learning in the real world • ***Flexible*** L&T for the offered ***learning activities*** • Flexible L&T for self-regulated learning and group work • A collaborative virtual and/or physical workspace is ***constantly accessible***

Assessment: how is the students' learning assessed?

Fig. 1. The CBL Implementation Continuum

3 FACILITATING CBL IMPLEMENTATION WITH AN ONLINE TOOL

An online interactive tool has been developed to guide teachers in using the CBL Implementation Continuum when (re-)designing courses. The tool combines the continuum with an evidence-based database of practical advice on how to transition to higher levels of CBL intensity. The advice database was collected from CBL practices and experiences at the University of Twente and knowledge on CBL implementation available in the literature. The tool first asks users to indicate the current CBL level of their course and the desired one for each curricular component. Based on the users’ input, the tool visually presents the gap between current and desired levels of CBL in the form of a spider web. Then, based on the presented gap, the tool compiles an advice report on how the users can bridge the gap between the current and the desired levels of CBL intensity. The tool is also designed to gather user feedback for regularly updating and continuously improving the offered advice and the level descriptors.

4 CONCLUSIONS AND FURTHER WORK

The CBL Implementation Continuum offers a practical approach for integrating CBL into higher education and suggests that courses can gradually evolve towards CBL innovation. Such a perspective can foster an increase in CBL acceptance in higher education. It prompts teachers to capitalise on what they are already doing in their courses and add new CBL elements to their curriculum step by step.

Notably, we present the CBL Implementation Continuum as a heuristic prototype. Intense CBL level descriptors were derived from literature, which details elements common to CBL, while Moderate and Mild level descriptors were heuristically deduced from CBL practice at the University of Twente. Moreover, the presented model does not consider the CBL-compass of Van den Beemt et al. (2023), as their work was published after the continuums were defined. Thus, we endorse further developments of the model and the level descriptors as new knowledge on CBL emerges.

In addition, as Van den Akker (2006) noted, while the emphasis of curriculum design on specific Spider Web components may vary, alignment is crucial for maintaining coherence. Teachers using the CBL Implementation Continuum should be aware that strengthening the intensity of one component while neglecting another could jeopardise constructive alignment. As such, they should remain mindful of this risk and adjust their approach as needed.

The CBL Implementation Continuum invites new research endeavours, which can considerably contribute to the scientific understanding of the educational approach. For instance, the model and the tool can be used in research on CBL to operationalise and measure the levels of CBL implementation. Furthermore, investigations could explore the impact of varying levels of CBL intensity on students' learning and skill development. Additionally, empirical recommendations on the most appropriate intensity levels for a course could be explored based on factors such as classroom size, course boundary conditions, and long-term curricula goals.

ABSTRACT

The objective of this practice paper is to describe and analyse the use of online learning tasks on engineering mathematics and physics courses. The development of learning tasks was inspired by the promising effects of gamification techniques in higher education. Hence, some gamification elements, such as bonus points and immediate feedback were integrated into the learning tasks. Course results and student feedback demonstrate the positive impact of gamification of online learning tasks on students' motivation and learning. In the end, further possibilities of increasing the number and repertoire of gamification techniques in engineering mathematics and physics courses are discussed.

1 INTRODUCTION

Many universities are currently developing domestic and international distance learning programs and other means to provide distant and continuous learning experiences in engineering. These often result in growing student intake as well as increasing diversity in the starting level knowledge and skills of the students. This situation, in turn, calls for the development of motivating and pedagogically meaningful online tasks with diverse and continuous automatic evaluation.

Well designed and constructed online tasks can simultaneously increase students' understanding of the topic and their motivation. One advocated approach for creating these is the gamification of education and game-like elements, such as scores, rewards, and challenges, have been shown to have the potential to promote learners' motivation, engagement, and performance (Alomari, Al-Samarraie and Yousef 2019). Points, leaderboards, badges, and levels are the most often used gamification techniques in university education (Alomari, Al-Samarraie and Yousef 2019) as well as in engineering education (Milosz, and Milosz 2020). Points and badges refer to rewards assigned for completing a task, leaderboards to display the ranking of the players, and levels to the variance of difficulty of player's actions (Milosz, and Milosz 2020).

The fifth most common gamification technique used in engineering education is feedback, which helps the players to avoid getting confused or lost (Milosz, and Milosz 2020). In learning situations, the feedback from game-like tasks can offer a constructive way to communicate that there was a mistake in the student's work, but also to praise them for a task well performed (Yong et al. 2021). Research shows that feedback is an integral part of learning and a pre-requisite in constructing new information structures (Yong et al. 2021), (Krause, Stark and Mandl 2009). Learning is more efficient the more often personalised feedback is received. In game-like tasks, errors and mistakes can be corrected based on instant feedback and hints. Mistakes should not be overly avoided but they should be seen as a way to improve one's learning (Yong et al. 2021).

Solving mathematical problems provides good grounds for gamification. Correct answers can be rewarded with points or badges, the requirement level can be adjusted through the complexity of the problems, most typical mistakes can be pointed out through hints and feedback, and the collected points can be used as the basis for leaderboards or progress bars. In addition to learning mathematics, gamification elements can also foster students' learning skills when they plan for the best gaming tactics, and even their interaction skills when they consult their peers for better success (Ariffin et al. 2022).

Online learning tasks with gamification elements encourages and motivate students to participate more actively in the learning process. The active role of the learner improves learning results. The active role of learner is included in the constructive learning theory (Hui, and Mahmud 2023). According to the constructivist learning theory, the learning process is self-directed and that creates new understanding and knowledge for the learner (Agarkar 2019).

In our work in university-level engineering education, we added game-like elements to online learning tasks in physics and mathematics. Here, we present our experiences on the effects of interactive online tasks on student learning and motivation from one such course, 'Basics of Vibration and Wave Motion'.

2 METHODOLOGY

2.1 Description of course implementation

The bachelor program first-year physics course (Basics of Vibration and Wave Motion) utilizes weekly independent online assignments. This course is worth two ECTS credits and it extends over seven weeks. The course includes lectures, assignments, independent weekly online exercises, and an examination at the end of the course.

2.2 Evaluation of the course

At the beginning of the course, the students are presented with the evaluation criteria. The course grade is determined by the examination at the end of the course. The final online examination includes 5 tasks with 10 points each, resulting in 50 points as the total maximum.

Additionally, it is possible for the students to raise their accepted grades by one by independently completing weekly online tasks. These voluntary tasks provide a maximum of 6 extra points (EP), based on equation (1), where r indicates the percentage of correctly solved weekly extra tasks.

$$EP = \frac{r}{100\,\%} \cdot 6 \tag{1}$$

For example, if the student achieves 35 points from the exam and has completed 69% of additional tasks ($EP = 4.14$), the student receives a total of 39.14 points. The final grade is assigned according to Table 1.

Table 1. Determination of grade from points

Grade	Points
0	< 23
1	23 - 28
2	29 - 34
3	34 - 40
4	41 – 45
5	46 – 50

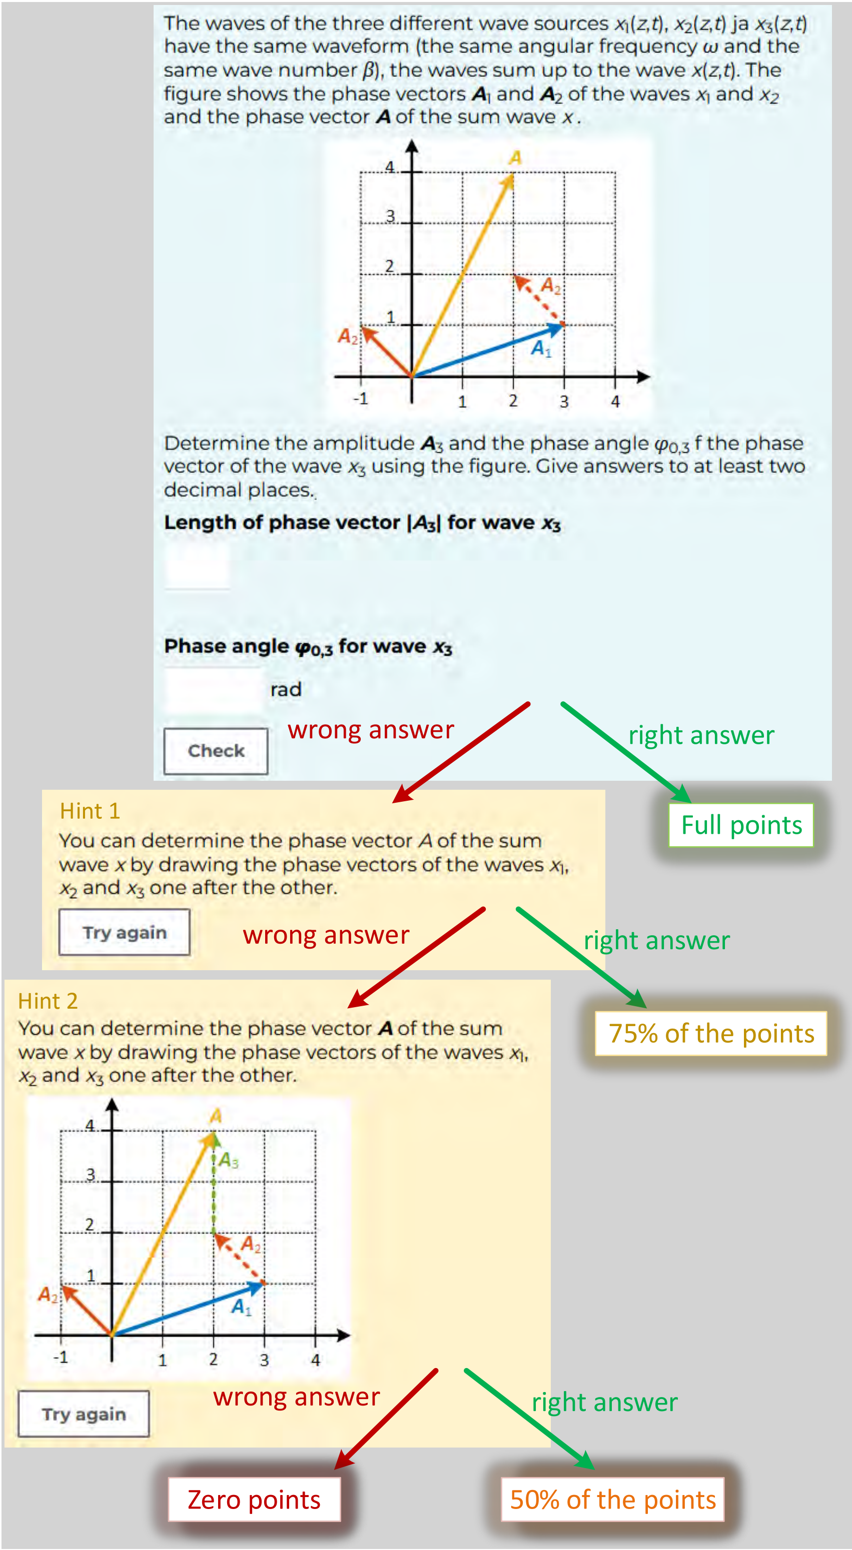

Fig. 1. Example on a numerical question and the scoring principle.

2.3 Online learning tasks

The weekly online exercises of the study unit are diversely implemented. By completing them, students' learning from the weekly subject is measured and deepened. The exercises are evaluated automatically and gamification elements like instant feedback as well as interactive hints are utilized. The exercises involve multiple choice questions, image interpretation and calculation tasks.The student gets instant feedback about if the answer was right or wrong. If the answer was right the student gets full points. If that is not the case the student gets a hint. The new trial gives 80% of the maximum points as a result of success. The student can have 2 or 3 new trials depending on the question. In figure 1, an example on numerical question is shown.

3 RESULTS

3.1 Tables

Thetask completion rate, lecture attendance and participation in either contact or video tutorial session have been recorded weekly, with results shown in Figure 2.

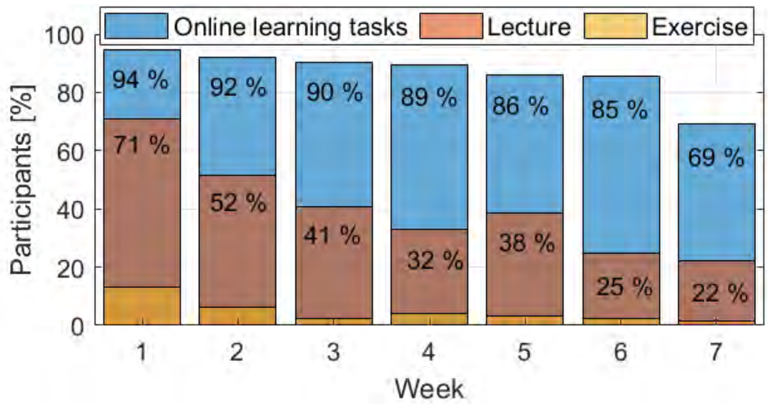

Fig. 2. Students‘ completion rate of online tasks and attendance on lectures and exercise/tutoring sessions in percentage.

The arithmetic mean of online task completion was 87% of students, lecture attendance 47% and exercise session attendance 15%. Comparatively, students were significantly more active in doing the online tasks. The conclusion is that despite these tasks being also in practice optional, students were motivated to complete them. To explore the benefit between completing online tasks and learning results, the arithmetic mean of the final grade for each quintile of online task completion has been observed in Figure 3.

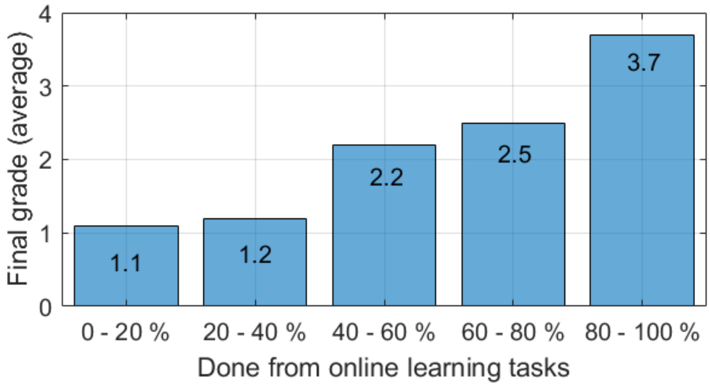

Fig. 3. Correspondence between online task completion percentage and final grade.

Students who have done more than 80% of online tasks had a final grade average of 3.7 (out of maximum 5.0) whereas students who had done less than 40% of online tasks had a final grade average of slightly more than one.

After completing the course, feedback was collected from the students, using the evaluation of several statements. Figure 4 shows the responses to the statement ”*Course’s online learning tasks supported my learning*”.

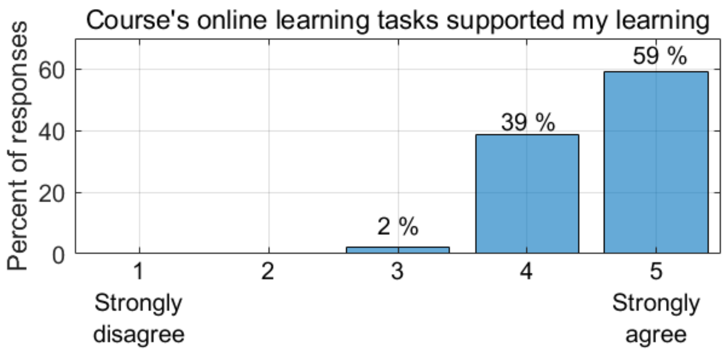

Fig. 4. Distribution of replies to ”Course’s online learning tasks supported my learning” in percentage.

The arithmetic mean of the replies was 4.6 and the standard deviation was 0.5. A total of 59% of replying students strongly agreed that the online tasks supported their learning.

In free verbal feedback, students made the following comments, among others:

> ”*The online learning tasks were nice and just suitably challenging*”
>
> ”*Challenging tasks and rewarding when solved*”
>
> “*Online learning tasks supported learning a lot, especially because tasks have multiple attempts with hints*”
>
> “*Weekly online learning tasks motivate continuous learning*”

4 LIMITATIONS OF THE METHODS AND STUDY

Gamification of learning often focuses on teaching concepts with measurable outcomes, well-defined rules, and quantification. To embed qualitative tasks that involve reflection, interpretation, and critical analysis might be challenging but not impossible. Another limitation is to provide personalised and meaningful feedback, particularly on qualitative tasks. Moreover, gamification heavily focuses on grasping student's attention by giving immediate rewards, feedbacks and competition. Complex skills, such as critical thinking, logical reasoning, and narrative building might not be achieved by the gamification of simple exercises.

Our study was also conducted within limited subjects and a single university; it might be better to use more diversified approaches in future studies. The study period of the analysed courses is seven weeks, but results could differ if the study period is longer.

5 SUMMARY AND ACKNOWLEDGMENTS

Course statistics show that the students were highly motivated to do the voluntary online learning tasks even though the effect of the tasks on the final grade was rather small. Completing online learning tasks was much more common than attending the lectures or exercises throughout the course and the temporal decline in the activity of doing the tasks was smaller than for other activities during the course.

The effect of online learning tasks for learning was evident, with a positive correlation between the task completion rate and final grade. Although active completion of the learning tasks was rewarded by increasing the final grade by a maximum of one category, this was not enough to explain the differences in grades between those having done a little and those having done a lot of learning tasks. Also, the student feedback indicated that the learning tasks strongly supported their learning.

Qualitative feedback from students revealed that the students perceived the online learning tasks to be suitably challenging, motivating and rewarding. The feedback in the form of hints was also appreciated. These, as well as the quantitative findings, are all well aligned with the discovered effects of different gamification techniques (Alomari, Al-Samarraie and Yousef 2019, Ariffin et al. 2022).

Based on this preliminary study, it is not yet possible to draw far-reaching conclusions about the effect of online tasks with gamification elements on learning. In the future potential feedback loops and further individualization of the course to the student level (e.g., adjusting difficulty level) should be considered. It would be also possible on the currently used learning management system to add other gamification elements, such as high score tables. These will be the next steps in the gamification of online learning tasks, which will be study in the future.

ABSTRACT

Computer-Aided Design (CAD) plays a vital role in the curriculums of mechanical engineering degree programs, empowering students to conceptualize and visualize their designs, thus enhancing their abilities as engineers. This abstract presents the implementation of a multi-CAD course conducted between 2014 and 2022, catering to hundreds of students from diverse disciplines, including mechanical and civil engineering. Throughout the course, student feedback was systematically collected to assess learning outcomes and measure the effectiveness of different learning tools and methods.

The course employed a range of tools, including automatically graded quizzes and a dedicated CAD model assessment system, which not only lightened the workload of teaching assistants in terms of assessment but also allowed them to focus on guiding and supporting students. Additionally, surveys conducted at the beginning and mid-term stages provided valuable insights into students' initial proficiency levels and their study patterns during the course.

[1] *Corresponding Author*

Kaur Jaakma

kaur.jaakma@aalto.fi

Significantly, the course successfully transitioned to fully online teaching during the period of remote instruction from 2020 to 2022. Lessons learned during this time were integrated into the regular practicalities of CAD course teaching, ensuring continued effectiveness and adaptability.

Improvements in student performance and feedback, observed during the implementation of the multi-CAD course, demonstrate the impact and success of the teaching methods employed.

1 INTRODUCTION

Computer-aided Design (CAD) has become a fundamental tool for mechanical engineers, resulting in the inclusion of CAD courses in university curricula worldwide. In certain countries, the prescribed amount of CAD instruction is even specified at the national level [1].

Traditionally, CAD education has focused on mastering software tools, and assessment has primarily relied on computer exercises or project work. Lectures are often provided alongside these courses to support students in completing the exercises and developing a comprehensive understanding of CAD model creation and its applications in areas such as simulations and manufacturing.

The primary objective of CAD education is to equip students with the necessary tools to support their future studies and professional endeavors. CAD courses are typically conducted during undergraduate studies, with the expectation that students pursuing master's level studies already possess these skills. The CAD modeling software commonly used is commercially available (such as Creo, Inventor, Solidworks, Solid Edge, NX), designed for professional use, which poses a challenge for students to learn. Although there have been attempts to develop CAD tools specifically for educational purposes[2], commercial tools remain prevalent due to their relevance in summer work, internships, and post-graduation employment.

Due to the critical nature of CAD knowledge for early-stage mechanical and civil engineers, the enrollment in basic CAD courses can be substantial, reaching as high as 400 students. This presents challenges in terms of available study spaces and the assessment process. Several studies have explored automating the grading process for 3D CAD models [3,4] aiming to expedite assessment and provide students with timely feedback on their learning progress.

This study outlines the structure of a CAD course, its evolution over the years, the feedback received, and how systematically collected student feedback has been utilized to enhance the course. To accommodate the large number of enrolled students, this course was progressively developed with a wide array of online tools, alleviating the burden of assessment for instructors and enabling a comprehensive overview of student progress. These tools and methods played a pivotal role in addressing the challenges posed by the COVID-19 restrictions from 2020 to 2022, facilitating a successful transition of the course to an online format. Subsequently, as restrictions eased, the course was gradually reintroduced in face-to-face teaching.

Additionally, this paper presents a new CAD course tailored specifically to mechanical engineering students, built upon the learning outcomes derived from the nine years of course development

2 STRUCTURE OF THE COURSE

The *Computer-aided Tools in Engineering* course is mandatory for three different majors offered by the School of Engineering: Mechanical and Civil Engineering, Energy and Environmental Engineering, and Built Environment. In addition to covering CAD tools for mechanical engineering, this course also introduces CAD tools specific to civil engineering and Geographic Information System (GIS) tools used in land surveying. The course attracts an average of approximately 350 students annually.

The course aims to achieve the following learning outcomes:

- Familiarize students with the basics of computer-aided tools, enabling them to implement these tools in their respective fields and evaluate their suitability for various subjects.
- Develop students' understanding of the characteristics and limitations of computer-aided modelling, as well as the practical methods of applying these tools in industrial and research contexts.

Spanning a duration of 14 weeks, equivalent to 5 ECTS credits, the course is divided into two seven-week periods. It incorporates weekly lectures covering different topics and weekly computer exercises conducted in computer labs. The course grading is based on a pass/fail system where 80% completion of each exercise is required. During the exercise sessions, students submit their completed computer exercises by demonstrating their models to teaching assistants, who then assess their work. Feedback from students is collected through an end-of-course survey, which gathers input on their overall satisfaction with the course grade, teaching organization, workload, and perceived benefits from the knowledge gained.

By adopting this structure and assessment approach, the course provides students with practical hands-on experience and allows them to apply their skills under the guidance of teaching assistants. Furthermore, the feedback survey serves as a valuable tool for continuous improvement and refinement of the course content and delivery

3 NINE YEARS OF COURSE DEVELOPMENT

This chapter highlights recent changes in the course syllabus, focusing on structural and tool-related modifications. The course has been part of the curriculum since 2014. *Table **1*** presents numerical data from the course feedback survey, starting from 2015. The feedback survey used a grading scale from 1 (fair) to 5 (excellent) for categories such as General Grade, Teaching Methods, and Usefulness. The Workload category had a scale of 1 (less work), 3 (expected amount), and 5 (too much work). The data from 2014 was excluded due to changes in the feedback survey form and scales, making it incomparable.

These changes aim to improve the course's learning experience and align with evolving educational practices. The feedback survey data provides insights into the effectiveness of these modifications, guiding further course development and refinement.

Table 1. Numerical data from yearly feedback surveys

Year	Number of respondents	General Grade	Teaching methods	Workload	Usefulness
2015	82	3,49	3,63	3,54	4,34
2016	69	3,87	3,96	3,42	4,66
2017	147	3,90	3,95	3,35	4,66
2018	107	3,94	4,08	3,52	4,64
2019	118	3,97	4,16	3,63	4,64
2020	120	3,83	3,81	3,54	4,59
2021	149	4,11	4,14	3,39	4,62
2022	122	3,49	3,89	3,39	4,50

3.1 Initial course (2014)

The initial course structure, depicted in *Fig. 1* , comprised a Common module and a choice of two modules from a selection of five. The Common module covered general topics such as data storage techniques and advanced computer model utilization, including learning diaries as part of the assessment.

Students selected one module in each period, participating in lectures and practical computer exercises held in computer labs. The modules introduced various software tools, including Autodesk AutoCAD (2D-CAD), Siemens Solid Edge (3D-CAD), PTC Creo (Mechanical Engineering CAD), Trimble Solutions Tekla (Civil Engineering CAD), and Esrin ArcGIS (Land Survey GIS).

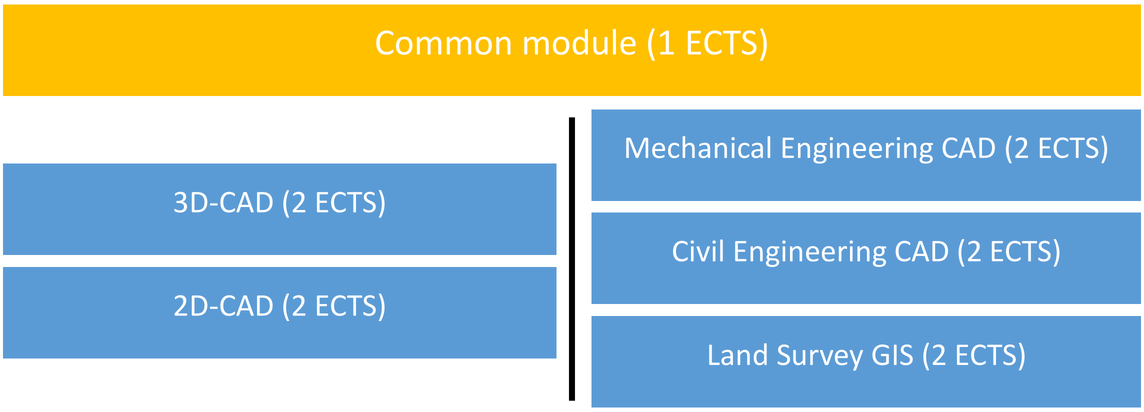

Fig. 1. Structure of the initial course

3.2 First iteration (2015)

In the first iteration of the course in 2015, the course structure was streamlined. The Common module was removed, and clearer module selections were introduced (*Fig. 2*). Now, students participated in two modules focusing on 2D and 3D CAD tools in the first period, followed by one selective module in the second period.

This change aimed to ensure that all students developed essential skills in both 2D and 3D CAD tools, which are crucial in fields like energy technology where layouts are in 2D and components are in 3D. As a result, the learning diaries were removed to allocate more time for practical training and hands-on experience with computer tools. This decision was strongly supported by student feedback.

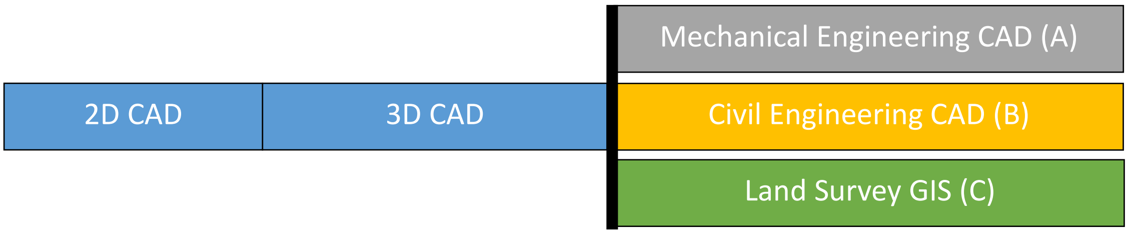

Fig. 2. Streamlined course structure

3.3 Quizzes (2017)

Creating engineering drawings according to standardized rules can pose a significant challenge for students. These drawings are intricate, requiring the memorization and recognition of numerous symbols, the creation of cross-sections and projection views, and the completion of header information fields. To support students in mastering these skills, an Engineering Drawings Symbols quiz was developed within the Moodle platform.

The quiz provided students with an opportunity to practice applying projection rules (as shown in *Fig. 3*) and recognizing various symbols used in engineering drawings. By engaging in interactive quizzes, students could enhance their understanding of these critical elements.

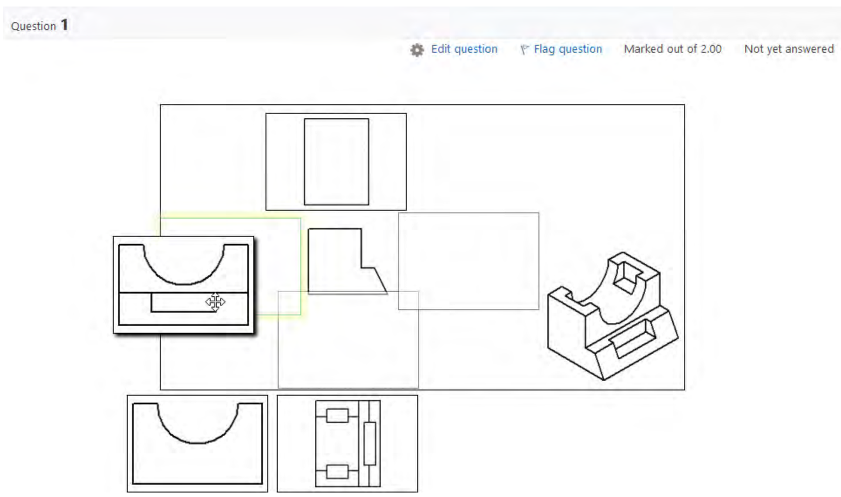

Fig. 3. An example question about projection rules, where a correct projection is needed to drag on its correct location

The quiz was automatically graded, and student had several attempts to get the required 80% right. The questions were randomized and selected from the pool of questions.

3.4 Additional Surveys (2017)

In 2017, two mandatory surveys were introduced: the starting survey and the mid-term survey. These surveys aimed to collect more comprehensive feedback throughout the course, enabling timely adjustments and enhancing the student experience.

The starting survey gathered information on students' backgrounds, computer usage experience, general computer skills, and attitudes towards learning CAD. This data provided valuable insights into their starting point, allowing for tailored course adjustments.

The mid-term survey assessed students' progress in learning CAD and their attitudes towards computer-aided tools. By collecting feedback during the course, instructors gained a better understanding of students' experiences, identifying areas that required additional support or clarification.

3.5 Automatic Assessment Systems (2018)

The assessment of CAD models is a time-consuming task, often with variations among teaching assistants and teachers in the assessment process and criteria. To ensure the accuracy of engineering drawings, it is crucial to verify the correctness of the CAD models before proceeding further.

To streamline the assessment process, two automatic assessment systems were implemented in the course. The first system compared the shape of the model with a reference model (*Fig. 4*), while the second system modified the CAD model's parameters and evaluated its response to changes [3].

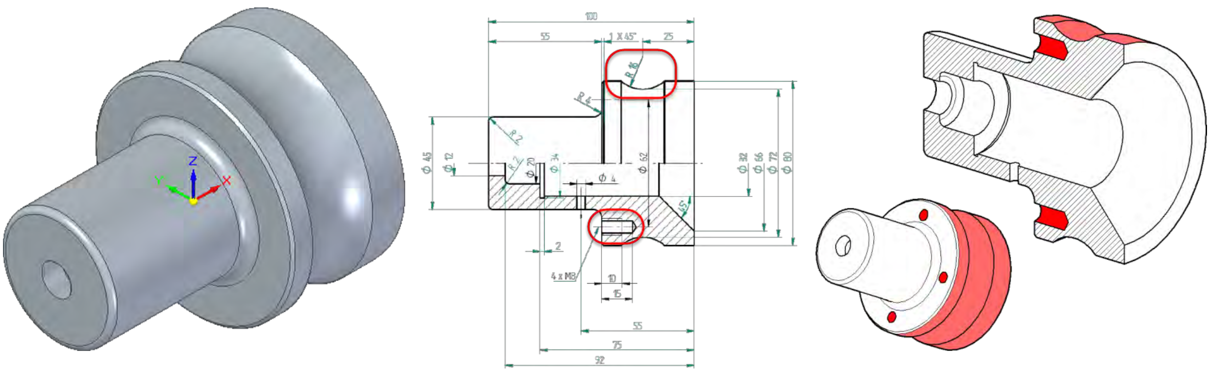

Fig. 4. From left to right: Student's returned model, comparison to reference model and mistakes made, feedback picture from the system highlighting errors in the shape [3]

By incorporating these automated assessment systems, the need for exercise demonstrations during computer sessions was reduced. This provided students with the convenience of submitting their CAD models independently, at their preferred time and location, which was well-received by the students.

3.6 Remote Teaching (2020-2022)

The year 2020 presented significant challenges for universities, with the sudden transition from in-person to remote teaching. Fortunately, the CAD course had existing online materials and tools in place for distributing and grading student work, making the transition surprisingly smooth. An online version of the course had also been developed beforehand [5].

The main challenges arose from installing necessary computer tools on students' personal computers. This was resolved by providing virtual computers with remote access, where all required tools were pre-installed. Exercise sessions were conducted via MS Teams, allowing students to share their screens and seek assistance from course staff.

The shift to remote teaching also impacted the submission of larger exercises. Previously, most modelling tasks were automatically assessed, with only a few more creative assignments demonstrated during computer exercises. However, in the remote setting, students were asked to create demonstration videos showcasing their models and their performance, as creative tasks without predetermined correct answers could not be assessed automatically.

4 CURRENT INPLEMENTATION

Following the renovation of the bachelor program, the previous common CAD course was replaced with two discipline-specific courses: mechanical engineering and civil engineering. The new mechanical engineering CAD course continues to utilize the tools discussed in the previous chapter. With this change, the number of students decreased from over 400 to approximately 250. Since it is now a single-discipline course, only one mechanical engineering CAD software, PTC Creo, is utilized.

This shift in discipline provided an opportunity to enhance the mechanical CAD teaching by incorporating more advanced modelling techniques, including skeleton and surface modelling. Consequently, the grading system was modified from pass/fail to a scale of 0-5 (0 representing fail and 5 representing excellence). This change was requested in the feedback received, as it allows for better recognition of students who invest time and effort in learning the tools and methods, rather than simply aiming to pass the course with minimal effort.

5 DISCUSSION

The CAD course received positive feedback from students since its inception. While there were concerns about the course's relevance to land survey and real estate economics students, the increasing demand for 3D models and evolving industry trends justified the inclusion of CAD skills in their education.

The introduction of quizzes and additional surveys in 2017 had a minor impact on feedback grades. The engineering drawings quiz aided students in completing their tasks, resulting in a slight reduction in perceived workload.

The implementation of automatic assessment in 2018 improved classroom guidance by allowing teaching assistants more time to assist students during computer exercises. However, it increased the workload for responsible teachers as the system identified more modeling mistakes, necessitating additional effort to address and rectify them. Clearer guidelines for automatically assessed models can help mitigate this issue.

The experience of remote teaching in 2020-2022 yielded varying feedback grades. The initial drop in 2020 can be attributed to the sudden transition, while the subsequent increase in 2021 reflects familiarity with remote teaching methods. The decline in feedback grades in 2022 may be attributed to the hybrid nature of teaching, causing confusion among students.

Future development of the course includes creating self-assessment quizzes on key tools and methods and providing in-depth knowledge on advanced CAD modeling techniques.

The learnings from the CAD course development include the need for careful assessment planning, as more precise assessment methods can increase the workload for course staff. Manual checks are still necessary despite the implementation of automatic systems. The previous pass/fail grading system, while ensuring uniform learning, posed challenges in managing missing assignments and caused prolonged course completion. The new course addresses these issues through a wider grading range, recognizing that students may have diverse learning preferences.

Keywords: *gender, mechanical engineering, Germany, digitalisation, study programme choice*

ABSTRACT

In Germany, women are still dramatically underrepresented in the fields of STEM, especially in engineering: less than 25 percent of engineering students are female. Correspondingly underrepresented are women in engineering positions, too. Research has shown that diversity in the work force is crucial to develop successful solutions for a complex and sustainability-oriented world.

Therefore, our ongoing research project (01FP22M01), funded by the Federal Ministry of Education and Research (BMBF), focusses on the underrepresentation of

yves.jeanrenaud@lmu.de

women in STEM, especially in mechanical and plant engineering. Using mixed methods of qualitative interviews and quantitative online surveys with female pupils, students and employees, as well as industry representatives, to create a comprehensive and multi-perspective picture of the conditions of engineering education and jobs. Thus, we can show what enables or hinders the recruitment, networking and initiative of women in engineering.

This practice paper therefore highlights the environment of engineering education and professional formation along the life course and the application of educational concepts in the light of digitalisation. However, because the research project is currently at the stage of implementing the survey and interviews, first empirical results are not yet available. Therefore, this paper will present the research project’s background, the methodological approach and nonetheless focus on digitalisation and conceptualises how to shed light on the use of digital technologies in engineering education and professional development throughout careers.

1 INTRODUCTION

1.1 Underrepresentation of Women in STEM

The proportion of women[2] in STEM[3] subjects, particularly engineering and computer science courses that are central to mechanical and plant engineering[4], remains low and is rising only slowly (Statistik der Bundesagentur für Arbeit 2019; Jeanrenaud 2020, 8–23; Destatis 2021a). At the same time, mechanical and plant engineering is a key industry for Germany in which enormous disruptions due to advancing digitalisation processes (cf. Kagermann et al. 2013) can be observed and are still expected (cf. TCS 2017). This is why these subject groups electrical engineering/information technology, computer science and mechanical engineering/process engineering are of particular interest.

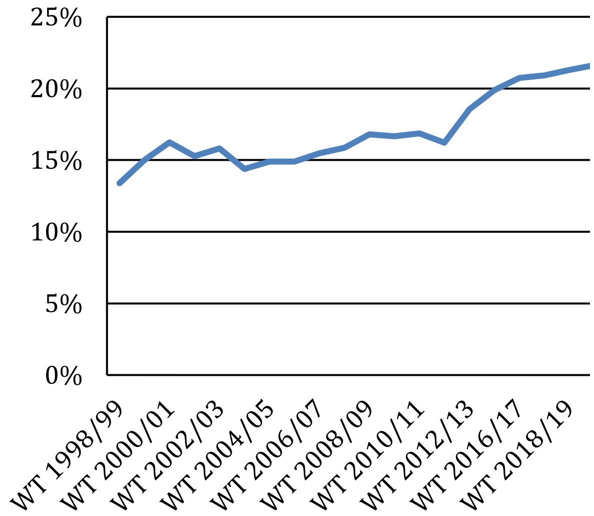

Fig. 1. Women's Proportion Among Female First-Year Students for Mechanical and Plant Engineering[4]

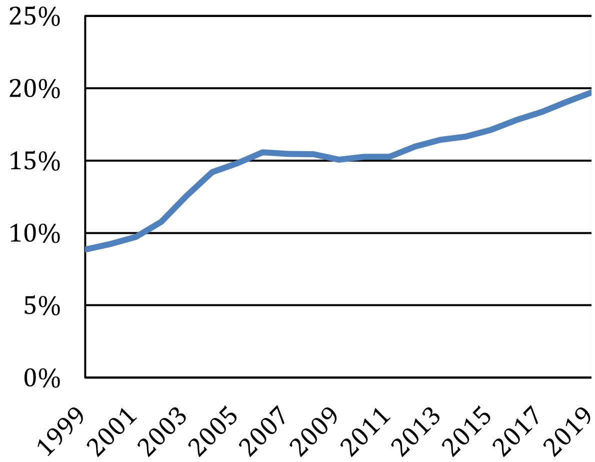

Fig. 2. Women's Share of Successfully Passed University Examinations for Mechanical and Plant Engineering[4]

While the proportion of women in the first semester of the subjects in question (Fig. 1) has risen from 13.39 percent in the 1998/99 winter term to 21.62 percent in the 2019/20 winter term (Destatis 2021a), there has also been an increase in the proportion of women passing university examinations in these subjects (Fig. 2) from

---

[2] Even though gender is not exclusively thought of in binary terms on a theoretical and empirical level, but rather takes on ambivalent self-attribution and attribution to others as a structuring social category. Women are spoken of here in order to make this category tangible in terms of social and labour market policy. Thus, when we speak here of gender categories such as women and men, we are referring to persons in empirical data as well as theoretical considerations who define themselves as such (situationally and performatively, temporarily if necessary) (cf. Bereswill 2014).

[3] STEM is understood as abrvearion for the subects of Science, Technology, Engineering and Mathematics

[4] Following (Thomsen, Schasse, and Gulden 2020), these are the five subject groups in the subject classification of the German Federal Statistical Office (2020): Engineering, general (61), mechanical engineering/process engineering (63), electrical engineering/information technology (64), transport engineering/nautical engineering (65) and computer science (71). All together this group contains 46 subjects.

8.8 percent in 1999 to 19.73 percent in 2019 (Destatis 2021b). But women engineers in mechanical and plant engineering continue to be underrepresented even compared to STEM subjects as a whole, which have more than 26 percent of first-year students and STEM degrees in women's hands at more than 31 percent (Jeanrenaud 2020, 8–12).

However, a significant dropout of female graduates into other occupations and inactivity can be assumed, as Thomsen et al. (2020, 20) showed: only 18.5 percent of female graduates were found in a core occupation of production and manufacturing about twelve to 18 months after their engineering degree. This is despite lower dropout rates than men (Thomsen, Schasse, and Gulden 2020, 13; Destatis 2021b).

This in turn means that women are still not participating to the same extent as men in the shaping, employment and acquisition prospects and the growth in importance of digitalisation in mechanical and plant engineering, which is not only problematic from an equality perspective, but is also becoming increasingly difficult for Germany as a business location with regard to the specific STEM skills shortage (cf. BDA 2020). Because STEM professions in general, and especially core professions in mechanical and plant engineering, are of particular importance in the course of the accelerated digitalisation of many areas of society – industry, work, education, social life (cf. Frielingsdorf 2019). Such are STEM studies themselves (cf. Anger, Koppel, and Plünnecke 2016), it is particularly worthwhile to take a closer look at women's choice of field of study and career entry explicitly against the backdrop of trends and changes with disruptive potential for the mechanical and plant engineering industry as a core STEM sector (cf. Orendi 2019) in terms of an analytical looking glass.

Because it can be assumed that the underrepresentation of female engineers in mechanical and plant engineering is due to both cultural and structural causes (Jeanrenaud 2020, 22–30), the research methodologically lends itself both to a look at individual career and life trajectories and to linking these to social and organisational contexts. Therefore, the basic principles and framework conditions are to be analysed with regard to the sustainable recruitment of women for STEM professions in research and innovation.

1.2 Project’s Goals

The aim of the project is therefore to develop recommendations for action for industry, science and politics in order to be able to react in an empirically sound manner to the underrepresentation of women in STEM fields (cf. Jeanrenaud 2020) and to identify which support services, especially for SMEs as well as schools and universities, could be specifically designed for this purpose. In this way, a cultural change should be initiated and promoted in the long term, which will bring more female STEM graduates into industrial companies and anchor them there in the long term, also taking into account the diversity of the special life situations of women.

Therefore, not only the active study choice orientation of female pupils should be reflected, but also the choice of female STEM students should be surveyed and analysed retrospectively. Furthermore, the question of factors in the course of STEM studies and in the transition to professional life is also in the focus of the project. Therefore, female STEM graduates are to be considered. This enables systematic access to the framework conditions in STEM professions and study course selection processes, which can be used to analyse the factors for successful recruitment, networking and successful anchoring of women in mechanical and plant engineering as an exemplary STEM core industry.

To this end, the following questions will be examined:

1. Where is the drop-out: why do below-average numbers of female graduates from engineering core subjects and computer science find their way into mechanical and plant engineering? At what point in the pathway and how do they get lost?
2. How do women engineers decide on specific courses of study, different companies and industries in the age of advancing digitalisation?
3. In this context, it is particularly interesting to see what role the design of the recruiting process plays (from university and company presentations to job advertisements and on-boarding, etc.).
4. What opportunities do digitalisation and other disruptive topics (e.g. new work, cf.Tarnoff and Weigel 2020) present for the mechanical and plant engineering industry (Orendi 2019) to attract more women engineers?
5. What is the role of (company) training in the course of talent retention and management? Studies (cf.Ebner and Ehlert 2018) indicate that, contrary to common assumptions, these have the potential to reduce churn and thus create individual career stability.

In order to be able to comprehensively research these questions, a mixed-method approach of qualitative and quantitative empirical methodology is particularly suitable (cf.Helfrich, Bollier, and Heinrich-Böll-Stiftung 2015; Johnson, Onwuegbuzie, and Turner 2014; Burch and Heinrich 2015). Further specific questions and sub-dimensions will probably be differentiated in the concrete preparation and in the course of the study.

Therefore, vectors and approaches for measures and projects to increase the proportion of women in STEM fields of particular importance for future-oriented and demand-oriented research and innovation, namely electrical engineering/information technology, computer science and mechanical engineering/process engineering, will be identified and condensed on a theoretical and empirical basis. These are based on the current state of causal research and suitably tailored empirical studies. Subsequently, appropriate measures as well as needs for action and, if necessary, further research, will be identified, which equally take into account the diversity of women's life situations, can be used multidimensionally and are correspondingly promising.

2 METHODOLOGY

2.1 Empirical Concept

Based on the goals and questions of the project, it is necessary to focus the study on empirical research into the transitions from school to university and from university to work and the change of jobs and/or companies in the course of life. The primary objective is to investigate the decision-making processes that speak in favour of or against a particular job in mechanical and plant engineering for female engineers.

Since cultural and structural reasons for this are the focus of the research interest, their effects on individual occupational and career paths will be ascertained by means of qualitative, problem-centred guided interviews (cf. Kurz et al. 2009; Witzel 2000; Meuser and Nagel 2009, 2018) with female students and engineers. Digitalisation should always be included as a cross-cutting theme and the question should be linked to it of what it changes in relation to (professional) decisions, careers, fields of activity and opportunities for female engineers. Furthermore, the attractiveness, opportunities and limitations of new work and working time models for female engineers (cf.Pugh 2017), which are further promoted by advancing digitalisation, should be addressed and evaluated in the interview. At the same time, the perspective of the companies should not be neglected, which is why a survey using a standardised online questionnaire of people in management positions from industry is also planned.

The interviews take place by (video) telephone with five cohorts of approximately ten persons each who are pursuing or have completed a university degree in a STEM subject relevant to mechanical and plant engineering and with a particularly low proportion of women.

The five cohorts of female engineers (I to V) are oriented to the time of the beginning of the study and, like the contact persons of the companies (VI), are recruited via a snowball system of various actors in the field (Schnell, Hill, and Esser 2018, 249) (associations, universities, female engineers/networks, etc.). In order to obtain a representative picture of the mechanical and plant engineering industry in Germany, approximately 380 responses from the approx. 21’600 companies nationwide (VdVC 2021) should be sought for a simple stratified random sample ($e = 5.0, z = 1{,}96$).

In order to obtain a picture of STEM women that is as diverse as possible, attention is paid to geographical, subject-related and biographical aspects (migration, proximity to education of the parental home, etc.).

2.2 Interview Cohorts

Empirical cohorts for the interviews are planned in five cohorts (I to V):

I. Schoolgirls in the process of choosing a course of study (approx. 17 years old)
   The main focus here is on study orientation motives, role models, the influence of gender roles and stereotypes.

II. Female STEM students (first / second semester)
Finding one's way in the degree programme, dropout and transfer issues as well as academic success are central to these interviews.

III. Advanced female STEM students (fifth / sixth semester)
These interviews focus on academic success, career planning and shaping one's life.

IV. Female STEM graduates (approximately one year after graduation)
Here, experiences of the transition from study to work, finding a job, aspirations and ambitions, life planning and the associated impressions are still very fresh and therefore the focus of research interest.

V. Young professionals
Approximately three years after STEM graduation. There are good opportunities for job mobility here, as 50 percent of male and female engineers are likely to have changed jobs for the first time after about 24 months, women even more often than men (Ambrasat et al. 2011). The women here are on average still under 30 years old and in the "rush hour of life" (BMFSFJ 2012). The issue researched here is the sustainable anchoring in the STEM profession.

Furthermore, the project deems it necessary to include the companies' perspective within the fields of mechanical engineering and plant engineering.

VI. Company perspective.
For this purpose, contact persons in management positions from companies will be interviewed in order to ascertain their perspective on the questions and topics as well as on the basis of the first interim results arising from the interviews of groups I to V. The interviews will be conducted in the form of a questionnaire. In this context, importance is attached to differentiating between different regions (e.g. east/west, rural/urban environment), company size (international groups/SMEs, family businesses and various central branches of mechanical and plant engineering, which is significantly facilitated by the quantitative survey.

This compilation of data creates the most diverse empirical perspective possible within the constraints of a project's duration of 36 months on the choice of study and the career entry and retention of women in mechanical and plant engineering, as well as on the diverse effects of changes in the world of work.

The interviews are each designed to last between 60 and 120 minutes. This time span allows for an in-depth empirical examination of the complex topics of the study. At the same time, it is reasonably easy for the participants to fit into their daily routine. A total of approximately 50 interviews will then be transcribed and analysed using the method of Qualitative Content Analysis (QIA) (cf.Schreier et al. 2019; Schreier 2014) according to Philipp Mayring (cf. 2016) / Udo Kuckartz (cf. 2016). The analysis software MAXQDA[5] is used for this purpose (cf. Steinke 2007). The open source software Limesurvey[6] is used for the online survey of companies in the mechanical and plant engineering sector.

3 DIGITALISATION AS INTERVENTION

In order to shed light on the environment of digital and traditional engineering education along the life course as well as the application of digital educational concepts and practices, it is necessary to reflect on if and how digitalisation can be understood as a way to improve the participation of women in STEM. Therefore, the project aims to conceptualise digital practices in terms of tools (e.g. Zoom, MS Teams, Cisco WebEx etc.) and learning contents (e.g. open education resources – OER, acquisition of skills to use the digital tools etc.) as an intervention into pedagogical contexts. For the project's point of view, it is necessary to highlight learning in the digital context in higher education institutions as well as on the job.

The extent to which these digital practices and learning contents can be understood as a critical intervention, as a short-term external influence on autopoetic systems that can mitigate or redirect exclusions and repulsive effects for women in STEM, must be explored further. This is ought to shed light on the question of how digital practices enable more diverse lifestyles in STEM professions, too.

4 ACKNOWLEDGMENTS

The project on which this paper is based was funded by the German Federal Ministry of Education and Research (BMBF) under the funding code 01FP22M01. The responsibility for the content of this publication lies with the author. The ongoing research project is fully funded under the programme STEM Action Plan, Field of Action 3 "Opportunities for girls and women in STEM", "Strategies for enforcing equal opportunities for women in education and research (STEM)" and the thematic focus "Increasing the proportion of women in the STEM research and innovation process: Strengthening self-efficacy, initiative and creativity" (MissionMINT – Women shaping the Future). The project continues from October 2022 until September 2025.

ABSTRACT

Teaching Analysis Poll (TAP) has become an increasingly popular tool for evaluating teaching quality and enhancing student learning outcomes in higher education. It requires, however, additional human resources. This paper presents a modified version for easy implementation: Formative Teaching Analysis Poll (FTAP). It can be used by an individual educator and is nonetheless an effective practical method for practitioners in higher education to improve their teaching quality and enhance the learning experience of their students.

Based on a review of literature and personal experience using FTAP, in this paper we provide an overview of the underlying methodology of FTAP, its benefits, and how it can be effectively implemented in higher education. FTAP involves collecting formative feedback from students on various aspects of teaching and learning methods, formats, and quality. It may include instructional methods, course design, and student engagement. The collected data is then analysed to identify areas of improvement and to inform teaching practice.

This paper highlights the benefits of FTAP for educators, including the provision of valuable feedback and means to implement it into an ongoing course. FTAP not only contributes to enhance teaching performances but is a powerful instrument to involve students and learners in the design and creation of a learning environment based on their needs. Illustrated with a case example, we show how by actively engaging in the learning process students reflect on their individual needs and take ownership for their education. In conclusion, this paper provides practitioners in higher education with an experience based, practical guide to evaluate their pedagogical and didactical approach, improve teaching quality, and enhance student learning experiences.

1 INTRODUCTION

Current developments in engineering education have taken more account of the nature of professional activities in engineering. As Hadgraft (2017) shows, this is reflected in a paradigm shift in curriculum development away from 'first teach the fundamentals' towards 'start by engaging with the engineering problems'. On the didactical level, this development follows the 'shift from teaching to learning' (Barr and Tagg 1995) and strengthens student-centred teaching approaches (van den Beemt, van de Watering, and Bots 2023; Hadgraft and Kolmos 2020). Putting students at the centre means granting them greater self-determination and a higher degree of autonomy in the learning process. They do not determine what they learn, but how they learn in order to become mature learners (van Uum and Pepin 2023; Wright 2011; Jones 2007). At best, this is reflected in assessment and feedback, which is not summative but formative (Hoidn 2016).

For educators, another question arises: How can we ensure that teaching addresses the needs of learners? In other words, how can we continuously evaluate whether pedagogical and didactical goals are being achieved?

As a method for interim evaluation, the use of a Teaching Analysis Poll (TAP) has gained relevance since 2010, especially in German-speaking countries (Franz-Özdemir, Reimann, and Wessel 2019). In the following, we present this method and in particular address the obstacles to its implementation. On this basis, we make a proposal on how educators can implement this method in a low-barrier way. We argue that our modification as Formative Teaching Analysis Poll (FTAP) is particularly suitable to accompany engineering courses in higher education. We show this by means of an example and derive recommendations for action when implemented by engineering educators.

2 FORMATIVE TEACHING ANALYSIS POLL

2.1 Teaching Analysis Poll

Teaching Analysis Poll is a qualitative method for the interim evaluation of a course that focuses on learners and their learning process. Unlike quantitative, educator-centred final evaluations, TAP allows the results to be integrated into the ongoing course and to initiate adjustments in the conception or choice of methods (Stockmann 2016). An external person is involved in the implementation, e.g. from the evaluation department of the university. This person takes over moderation in the following three-stage process and is required because the educator must be absent during the first phase. In this first phase, the moderator leads a group discussion among learners, which is structured by the following three questions:

1. What aspects of this course help you learn? Please be specific.
2. What aspects of this course impede your learning? Please be specific.
3. What suggestions do you have for improving your learning in this course? Please be specific.

The results are then prioritised by learners and prepared by the moderator for the second phase.

The second phase consists of an evaluation discussion between educator and moderator. During the third phase, learners and educator discuss the results and, if necessary, derive measures for the remainder of the semester. These may also be documented in an agreement (Franz-Özdemir, Reimann, and Wessel 2019; Weiß 2019).

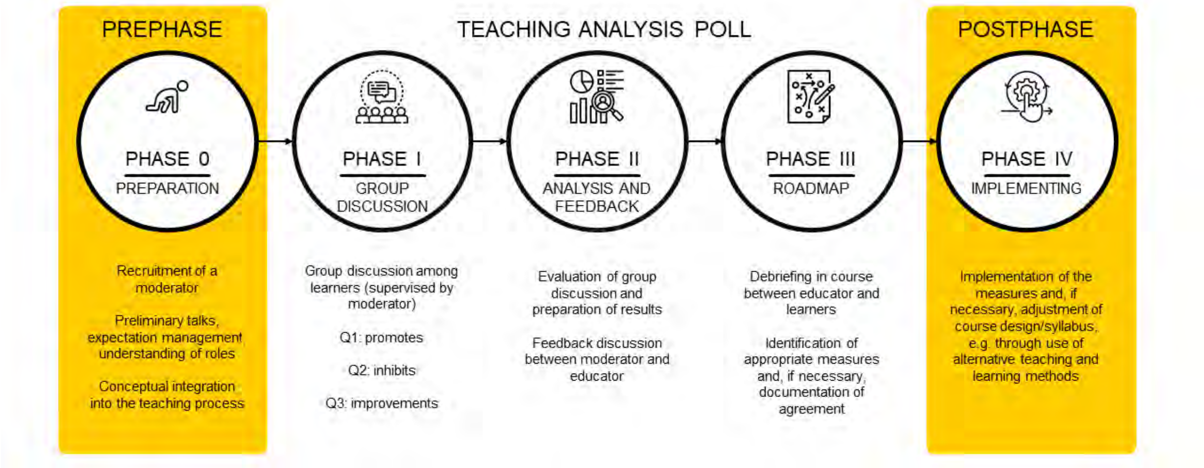

Fig. 1. Phases of Teaching Analysis Poll

Advantages of this method are obvious. It allows educators to assess their pedagogical assumptions and didactic concepts against the actual learning processes of their students, to identify needs for action and to derive measures. At the same time, this method lowers barriers for students to criticise because they do not have to fear being sanctioned for their criticism due to the involvement of a moderator as intermediary and absence of the educator during the discussion. After all, the educator is usually the same person who assesses learners' performances. Another advantage is that students are seen as equal partners in teaching and learning processes and are also given responsibility for successful design (Franz-Özdemir, Reimann, and Wessel 2019).

On the other hand, this method imposes high demands on the implementation, which can pose considerable obstacles. The biggest obstacle is undoubtedly finding a person to function as moderator. Although the literature consistently refers to institutions entrusted with quality assurance in teaching (Franz-Özdemir, Reimann, and Wessel 2019; Weiß 2019; Frank, Fröhlich, and Lahm 2011), human resources in particular are limited in these institutions as well. In our own university, for example, we approached various bodies and, despite numerous requests, were unable to recruit a person to moderate. This experience was decisive for the adaptation of the method as proposed in this paper. Another obstacle is the fact that this method requires an interruption of the syllabus in the ongoing semester. This makes sense from a conceptual point of view but can lead to undesirable interruptions particularly when educators apply student-centred teaching methods. For example, interruptions in the work on a problem-based project can lead to undesirable effects for the learners, of which a lack of commitment to the TAP may be merely the most obvious effect. For educators, these interruptions require a strict adherence to their semester planning, syllabus, and a reduction in content. Accordingly, educators need to be convinced of the benefits of the method, which in turn can be an obstacle for first-time implementation. Finally, we observe a limitation of the method in the one-time intervention. Due to the high effort involved, TAP does not allow for iterations and therefore does not permit any statements about the effectiveness of the measures taken subsequently.

2.2 Development of Formative Teaching Analysis Poll

We responded to the obstacles for implementing TAP and adapted the method to be able to use it in a more accessible way. The following six criteria were decisive:

1. Implementation of TAPs should not depend on the availability of (human) resources outside the course.
2. The method should be formative. Here, we understand formative evaluation as an evaluation process that goes beyond a one-time intervention.
3. The method should be applicable without interrupting ongoing learning. Thereby we want to ensure that learner-centred methods can unfold their didactic potential unhindered. We argue that student-centred methods benefit more from accompanying reflection than from interrupting evaluation. This makes the method suitable for use in a variety of engineering education courses.
4. The method should also be able to reflect and evaluate adjustments made based on prior feedback. Its accompanying character should enable educators to institutionalise it as an iterative process.
5. Educators must ensure that students are involved as equal partners in designing the learning environment and are taken seriously as experts for their (respective individual) learning processes.
6. To avoid censorship effects by not using an external moderator, there must (also) be a channel for anonymous feedback.

For TAP to fulfil these criteria, we had to find a way to integrate an evaluation not only as interim evaluation, but also as an accompanying process with the teaching and learning process. Here we coupled the method with another format, a learning journal. A learning journal is a written documentation of one's learning process that emphasises reflection on learning over the content learned (Park 2003; Johannsen 2021). Although we provide guiding questions for learners, we do not specify content or length of entries. For educators, we recommend using a digital tool because it allows asynchronous access to content by learners and educators alike. In addition, it features methodological overlaps with TAP. Using it as part of a FTAP is unique in that the questions of a TAP concerning (1.) helping, (2.) impeding, and (3.) improvable aspects are integrated here.[2] This allows educators to obtain feedback on each past session before the next one. Any other individualised feedback tool is, of course, equally suitable if it is used regularly by learners and evaluated by educators. Web-based instruments that allow anonymised data entry are particularly suitable for this purpose. Alternative easily used tools include ether pads or online whiteboards. All that needs to be ensured is participation to such an extent that the results can neither be individualised nor become meaningless due to the low number of contributions.

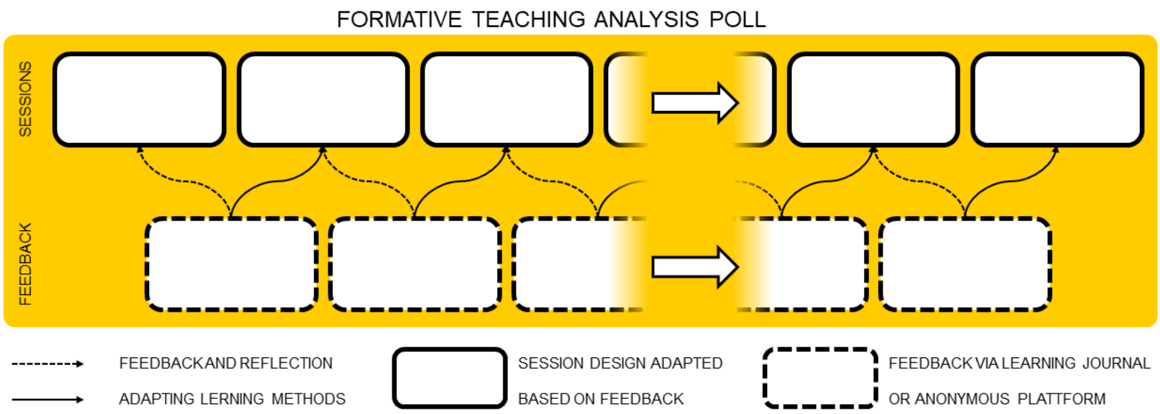

Fig. 2: Iterating Phases of Formative Teaching Analysis Poll (here in combination with Learning Journal)

Results can then either be systematically evaluated or used as a channel to pragmatically identify any need for action. Either way, each analysis should be based on a methodological approach. Due to reduced effort and with the aim of creating the best possible learning environment, especially when teaching and learning methods are used in which an educator has little experience, there is much to be said for the latter, pragmatic evaluation. In our experience, the time needed for each weekly evaluation is about one hour for a course with thirty learners. This is a reference value from which individual variations are possible. We found that it is good practice to always select the most important results at the beginning of each session and report them back. This allows learners to correct misinterpretations and to think about improvements on their own. They also experience that their contributions (can) have consequences for their own learning process. By making feedback loops an integral part of the course, the process character of FTAP is considered. In a final session reserved for discussion and reflection, we reflect on the course. As part of this reflection, an evaluation of the FTAP also takes place. We provide an insight into these results under 3.1 in the context of the case example. In addition, we conduct a summative (and therefore educator-centred) final evaluation. It is, of course, optional to use the final session in this way as it is optional to conduct an evaluation at the end.

[2] TAP can also be combined with management methods such as the stop-start-continue approach and made productive for higher education teaching (Hoon et al. 2015).

2.3 Evaluation

To investigate whether FTAP is effective and achieves the goals we set, we used the example of a course offered every semester and conducted a group discussion in the final session for a preliminary evaluation. As this session did not focus on the FTAP method, but rather reflected on the course, we decided to conduct a qualitative analysis. We evaluated the results of group discussions as well as entries from learning journals and anonymous feedback channels using a qualitative content analysis based on (Gläser and Laudel 2013). This analysis includes the contributions of eighty-seven learners. Because this paper is a practical report, we will limit subsequent comments to a poignant presentation within the framework of the following case example using illustrative statements. This also results in limitations of this evaluation, given that the focus is on FTAP and its implementation strategies.

3 IMPLEMENTATION

3.1 Case Example

FTAP was applied and evaluated in the course *Engineering for Impact*. It is an interactive seminar in which students use transdisciplinary methods to develop innovative, technology-based solutions for societal challenges. We use a variety of formats and methods to establish a practical relevance and to pave the road towards application in the spirit of the beforementioned paradigm shift in engineering education. Most notably is an involvement of guest experts from practice, who hold workshops with students in which they apply methods and tools to further develop their respective projects. As part of the assessment, students write a paper describing the problem in a scientific way and explain their solution in an oral presentation. As part of the assignment, they reflect on the social impact, identify stakeholders from the fields of science, business, society as well as politics and develop a communication strategy with suitable measures for implementation. We have published an exemplary demonstration in cooperation with Fraunhofer-Gesellschaft (Johannsen and Schraudner 2022).

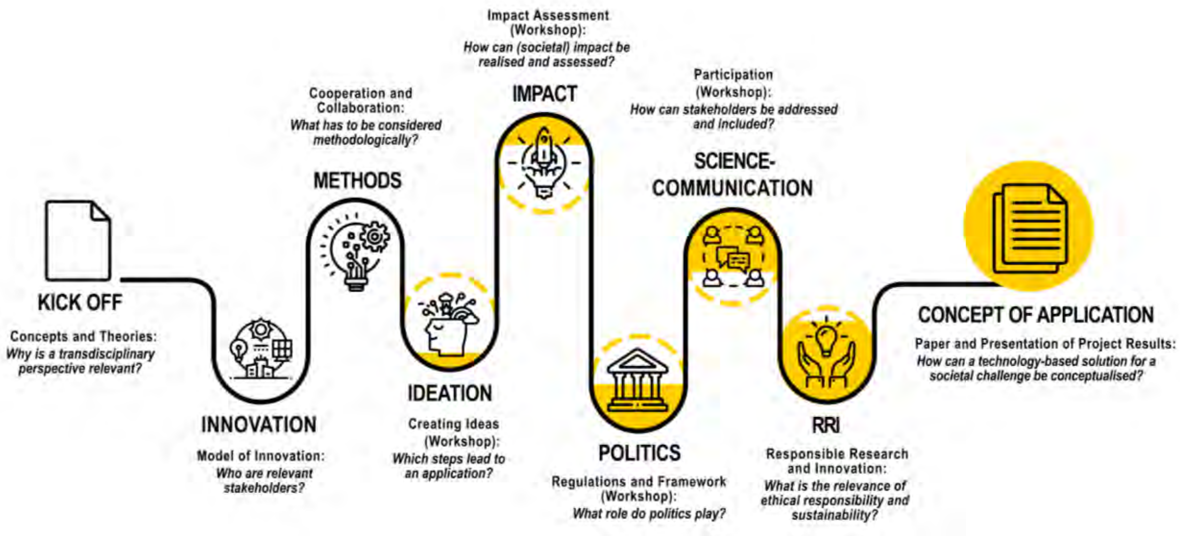

Fig. 3: Simplified Syllabus of this Case Example

Feedback we received from students we interpreted against the background of their project work. Overall, the evaluation has resulted in various clusters, three of which we present here as examples. In the following figure, the clusters are named and then illustrated with the students' own statements. All translations are our own.

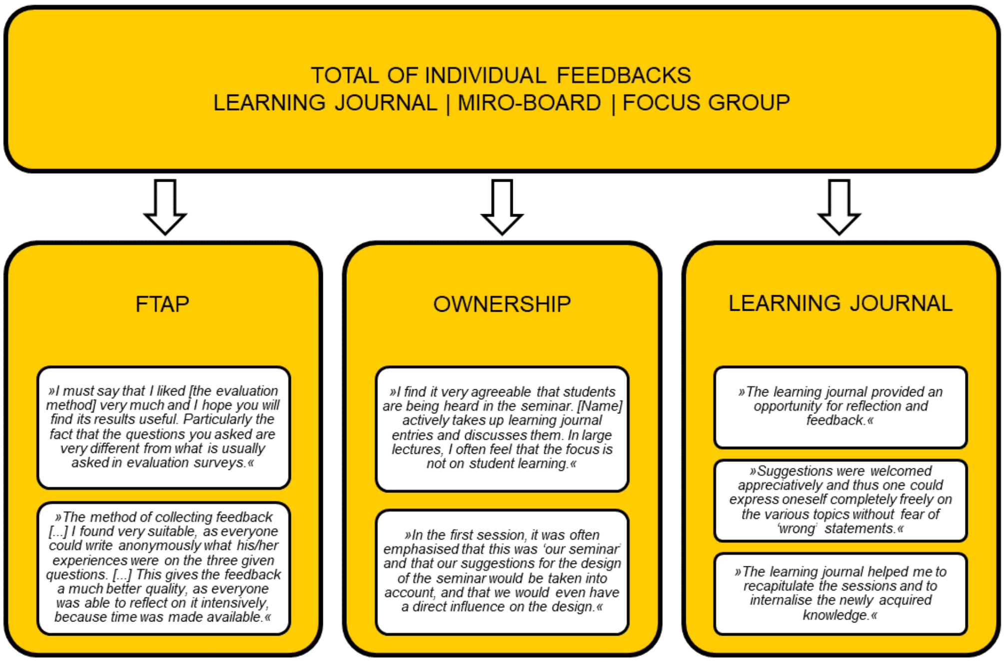

Fig. 4: Selected Results of Qualitative Evaluation with Exemplary Statements

The first cluster concerns FTAP, which is the subject of this paper. It is not an independently evaluated object, so not all students refer to this format. Nevertheless, it was repeatedly taken up and, above all, the inclusion of feedback in the course was a constructive contribution to its design. This is exemplified by the first statement, in which a student emphasises its usefulness. The second quote refers to the possibility of giving direct but anonymous feedback. Here, the contribution emphasises the quality of the feedback, which benefits from this integrated format because it makes it easy to accept it as an integral part of the course. As a result, students recognise its benefits, develop reflective capacities, and engage more willingly in reflective activities. This is in line with results of Power and Tanner (2023).

The second cluster refers to the role of students as co-creators of the course. The first quote highlights the function of learning journals as a channel for feedback for the design of a supportive learning environment by using feedback in iterative cycles to adapt used methods and formats in the course to needs of learners. While this quote is taken from a retrospective point of view, i.e. at the end of the semester, the second quote is taken from an entry in a learning journal following the first session at the beginning of the semester. It emphasises the importance of involving students from the beginning, taking them seriously as experts for their learning and sharing responsibility for designing their learning environment. Our results, hence, are in line with results of similar approaches (Zhang 2022).

A third cluster provides exemplary quotes about using learning journals as a format. We chose to present these results, because it played a key role in our conception, although it is not necessary for the implementation of an FTAP and can be replaced by other channels. Its particular benefit arises from the fact that students not only provide feedback, but are also given supporting structures, for example through guiding questions, which help them to achieve a more sophisticated level of reflection, both in terms of a critical appraisal of the content as well as the pedagogical and didactical framework (Hatton and Smith 1995). Here, too, appreciative interaction and a high degree of transparency about adjustments in the course helped to improve the learning environment, promote learning successes, and thus contribute to better results in the course overall. Transparency not only includes the implementation of measures, but also a justified rejection of student suggestions if these cannot be implemented.

3.2 Recommendations for Action

The path to this innovative, formative teaching evaluation can be taken without much effort. Those who want to introduce FTAP in their courses merely need time within the course, and willingness to engage in criticism, and make adjustments in collaboration with learners to improve their learning environment. We conclude by summarising our recommendations for educators who want to go down this path and plan to use FTAP in engineering education.

1. This format is based on voluntary participation of both educators and learners and serves the purpose of aligning expectations and needs of educators and learners alike. Handle results with due confidentiality.
2. Be prepared to (partly) give up control and share responsibility with learners.
3. Allow time not only to take in learner feedback but also to discuss it with them and derive appropriate adjustments from it.
4. Find a format that is compatible with the learning management systems (LMS) currently in use and does not require any additional preparation on either the educator's or the learners' part.
5. Be appreciative and take learners seriously as experts for their learning process.
6. Be transparent about both the changes you implement and the suggestions you discard.

Our experience is in line with Frank, Fröhlich, and Lahm (2011) that educators who show a sincere interest in successful learning in their course and who approach establishing an appropriate learning environment with scholarly curiosity benefit the most from FTAP. In this respect, it is a matter of attitude, because those who are as ambitious about investigating ways to improve their teaching as they are about their own research are embarking on the wonderful journey of improving engineering education together with learners through FTAP.

4 SUMMARY AND ACKNOWLEDGMENTS

FTAP is a method that allows formative evaluation of courses and provides formative feedback for educators, stimulates reflection, and promotes exchange between educators and learners to create a supportive learning environment and to increase learning success. Thereby, it can be ensured that education effectively addresses needs of learners as well as achieving pedagogical and didactical objectives. Considering that engineering education is undergoing a paradigm shift with more student-centred teaching and learning approaches, this ongoing alignment is of great importance. Therefore, FTAP is particularly suitable for educators who want to adapt their teaching and experiment with new formats, because it contributes to quality assurance with its iterative and agile stages.

Our special thanks are extended to the participants of the course *Engineering for Impact* at Technische Universität Berlin for their cooperative, open, and constructive participation, through which we learned with and from each other.

ABSTRACT

Laboratory activities are an essential part of an undergraduate engineering education. This paper focuses on evaluating the student experience of laboratory activities. We present a laboratory-specific survey used with large cohorts of students (200) about laboratory activities across an undergraduate Mechanical Engineering degree programme. The key question we try to answer is whether the results of the survey can be used to inform teaching decisions such as which activities need improvement; how to improve them; and to validate these interventions.

We present nine common questions that were used to evaluate activities across a programme. We present five years of data for five of the activites we assess – specifically those from the first year of the programme. The data covers pre-pandemic, lockdown, and post-lockdown periods. The data includes activities that have remained consistent, and activities where changes have been implemented.

For consistent activities, data show good repeatability, adding confidence to the method. The effects of interventions can also be detected. We define a significant change as being a multiple of the standard deviation, across years, when no interventions were used. We discuss the validity of the survey and conclude that, in practical terms, it is useful for informing teaching decisions.

1 INTRODUCTION

Laboratory activities are an essential part of an undergraduate engineering education. This paper addresses the challenge of *evaluating* laboratory activities. The purpose of a high-level evaluation across a degree programme is as follows. Firstly, to provide evidence of continued high quality to justify maintaining the status quo if applicable. Secondly, to identify opportunities for improvement and hence inform the rational allocation of teaching resource to these areas. For example buying new equipment or paying for staff time to improve materials or processes. In the second case, a closer look would be needed before making decisions; the purpose of the high level survey is to identify where attention is needed. Thirdly, evaluation can validate interventions.

Evaluation can consider different perspectives and stakeholders, for example an assessment of learning gains (Watai et al. 2007, Salim et al. 2013), process (Kotulski 2010), or student views (Stark 2016). The student view has been shown to play an important, if not essential, role in evaluating laboratory activities (Nikolic 2016). This paper presents and analyses a survey to evaluate the student experience of laboratory activites.

In this paper we briefly review literature on student evaluations. We present a survey methodology. Example results from the first year of a degree programme are presented, and we discuss the interpretation, validity, and application of the survey.

2 LITERATURE REVIEW

Student evaluation of teaching (SET) is well studied but controversial. A review by Stark (2016) identified the invalidity of surveys – due to bias – of student *judgement* (such as instructor effectiveness or professionalism), but stated that it may be valid to evaluate a student’s own experience. We therefore avoid seeking to identify e.g. ‘good teachers’, but try to identify good (or bad) ‘experiences’. A good experience is not the same as effective learning but it is a useful proxy that can be considered along with other types of evaluation.

The rich literature on evaluation tends to focus on classroom activities which are distinct from laboratory activities so not directly applicable. Evaluation of laboratory activities in general is challenging because there is also a diversity in the purpose and nature of laboratory activities across different disciplines and institutional cultures (Feisel and Rosa 2005). Despite this diversity, a common approach to evaluation across a programme is desirable for efficiency in deployment across a programme, and for higher utility – such as rational teaching resource allocation within a programme.

A small number of engineering laboratory-specific surveys are described in the literature. Nikolic (2016; see Ch.3, Ch.7 and Table 7-II) developed a common survey for laboratory activities. The survey used six questions, focussed on ‘impression’, content/information, ‘worthwhile learning experiences’, suitability of computers and other equipment, and condition of the laboratory. Repeatability was reasonable, and interventions could be detected. Most questions rely significantly on student judgements.

Corwin et al. (2015) evaluated course-based research experiences in biology, focussing on three dimensions: ‘collaboration’, ‘discovery’, and ‘iteration’. They used a 17 item survey after reducing from a larger bank of questions by testing for statistical validity. The strengths of Corwin et al. (2015) are the statistical validation of the survey; and the identification of key ‘dimensions’, which is a transferable notion and is experience-orientated as opposed to judgement orientated.

In the case of undergraduate engineering education the emphasis is slightly different to the course-based research that Corwin et al. (2015) evaluated so it cannot be directly applied. In this paper we present and analyse a survey that is ‘dimension’ and ‘experience’ orientated like Corwin et al. (2015), but practical in the sense of Nikolic (2016) by having a small number of questions and being applied across a whole programme. The key question we try to answer in this paper is whether the results of such a survey can be used to inform decisions about teaching.

3 METHODOLOGY

We surveyed students using nine standard, closed questions applied to all laboratory activities in their programme. The survey contains supplementary questions that vary year-to-year, and free text comments. In this paper, however, we focus only on the nine standard questions in the survey.

3.1 Nine standard questions

Due to the application of the survey across many activities, we limit ourselves to nine questions to avoid survey fatigue in the students. One student will answer nine questions per activity, for example first year students provide 45 total responses; for our second year students it is 72, which we judge to be a practical limit.

The ‘questions’ are positively worded statements listed in Table 1, answered with a 5-point Likert scale: strongly agree / agree / neutral / disagree / strongly disagree.

Table 1: the nine statements in the 2023 survey.
** = different in previous years; + = clarified from previous years.*

Short name	**Full statement**
Purpose	‘The purpose of the lab was clear to me.’
Conceptual	‘The lab session gave me a better understanding of the abstract concepts taught in the related module (e.g. energy, pressure, stress, entropy, current, resistance, etc.).’
Challenge	‘The lab session challenged me in a positive way’
Tech. comm. skills+	‘Preparing a report/presentation helped me develop technical communication skills’
Documentation and guidance*	‘The documentation and guidance for the lab session was clear, organised and well prepared. Consider: - Handouts, videos, interactive content - Guidance in the live sessions - Using the practical equipment (where appropriate)’
Engagement	‘I felt engaged in the experience and enjoyed the lab session’
Support*	‘I was well supported by GTAs or other staff during the lab session.’
Feedback	‘I received good feedback [link to College page about feedback] When answering this question consider feedback during lab sessions as well as the marks on your final report/presentation.’
Collaboration*	‘I was able to collaborate with my colleagues (to the extent required).’

Table 2: four statements that changed between years, and their previous versions. Multiple versions indicate multiple changes over different years.

Short name	Previously
Technical comm. skills	**Professional skills** – 'The lab session and report writing helped me develop professional skills' (2019,2020) – 'Preparing a report/presentation helped me develop professional skills' (2021)
Documentation and guidance	**Equipment** – 'I understood how the equipment worked and was able to use it as required.' (2019, 2020)
Support	**Motivation** – 'The lab session was motivating.' (2021) **Practical skills** – 'I learned new and useful practical skills' (2019, 2020)
Collaboration	**Knowledge** – 'I learned new things and reinforced what I had learned in the related module' (2019, 2020)

3.2 Selection of questions

The original nine questions were selected as a starting point based on practical experience, i.e. without a theoretical basis. Annual reviews with a team of activity leaders led to action plans, but we also discussed whether questions should be changed. The changes we made are given in Table 2 and are discussed here briefly.

A survey question about using equipment was refined to focus specifically on documentation and guidance – because this feedback is more actionable for teachers. A question about gaining knowledge overlapped with the question about 'conceptual' understanding, so was replaced by a question focussing on collaboration – a topic that we had previously omitted but was particularly sensitive during lockdown. The question about support reflects a growing focus on the support staff – typically PhD students – and replaced a question on 'motivation' which showed a strong correlation with 'engagement' so was judged to be redundant.

The nine themes that we present here partially correspond to dimensions that have been used in the literature. For example, collaboration (Corwin et al. 2015) and challenge (Kandiko Howson and Matos 2021) are common themes. There is a difference in the overall collection of themes used here because the focus is on discrete activities and on the laboratory. It would require further research to provide a rigorous justification for our 'dimensions'. Currently they have emerged from practice.

3.3 Analysing repeatability and sensitivity

Likert scores, s, range from 1 to 5. For large samples we can consider mean (average) values, μ, of the Likert scale (Derrick and White 2017, 2),

$$\mu = \frac{1}{n}\sum_i^n s_i \qquad (1).$$

where n is the number of responses and i is an index spanning all responsess. We also take an interest in the 'mean of means' μ_2 across years or across the dimensions of an activity. To analyse the repeatability, we consider the standard deviation, σ, of the values of μ over a range of m years:

$$\sigma = \sqrt{\frac{1}{m-1}\sum_j^m (\mu_j - \mu_2)^2}, \qquad (2).$$

where j is the year. More sophisticated approaches, such as omitting neutral responses, and other more advanced filters, did not have a significant effect on the results hence we use the simplest approach – given here – for clarity.

When the difference in the mean, between cohorts or between activities, is greater than the standard deviation ($\Delta\mu \gg \sigma$) we consider the student experience to have changed significantly, as opposed to there being variation between cohorts and/or due to sampling. 'Sensitivity', which is the smallest change, $\Delta\mu$, we can detect above the noise, is therefore an arbitrary multiple of σ, for example 3σ is a practical threshold.

3.4 Context

The survey was optional and anonymous for students and conducted in May each year after all the relevant activities were complete and feedback had been delivered. We conducted the survey from 2019 onwards and present data from 5 consecutive years. Response rates are given in Table 3. For brevity in this paper we only analyse activities from the first year of study. All activities were in-person except in 2021 when they were remote. The survey was conducted at a time when students could socialise, except in 2020 and 2021 when students were in lockdown while filling out the survey. During lockdown (2021) each activity was adapted to remote conditions differently, as summarised in Table 4.

Table 3: response rates and cohort sizes in the survey over five years.

2019	2020	2021	2022	2023
127/174 (73%)	89/172 (52%)	112/214 (50%)	74/199 (37%)	118/194 (61%)

3.5 Description of the activities

All activities involve a scheduled 2-3 hour activity in a laboratory, summarised in Table 4. Some activities involve mandatory preparation work. Most activities involve submitting work a week later to be assessed.

Table 4: Activities in year 1 of study

Activity (subject)	**Purpose and description**	**Lockdown (2021)**
Fairground (solid mechanics)	Introduction to lab work and report writing. Scenario about a fairground ride and drilling a hole. Measure strain on a plate. Write a report.	Data provided
Pipe flow (fluid mechanics, aka 'fluids')	Scenario about a customer complaint. Discovery based learning, testing pipes for pressure drops. Write a report.	'Human robot' in the lab live on Teams following instructions.
Steam plant (thermodynamics, aka 'thermo')	Practical experience of thermodynamic cycles. Measure performance of a steam plant. Consultancy scenatio. Group presentation.	Data provided
Mechatronics	Practical training on a series of DC circuits. Build, test and complete in-lab. Complete before leaving the lab.	Human robot
Materials	Tensile test of aluminium allous; hardness test of carbon steels. Write a report based on a template.	Data provided

4 RESULTS AND DISCUSSION

Fig 1. shows results for five consecutive years, for four of the five different activities in the first year of the programme. The top row of Fig. 1 shows the two higher

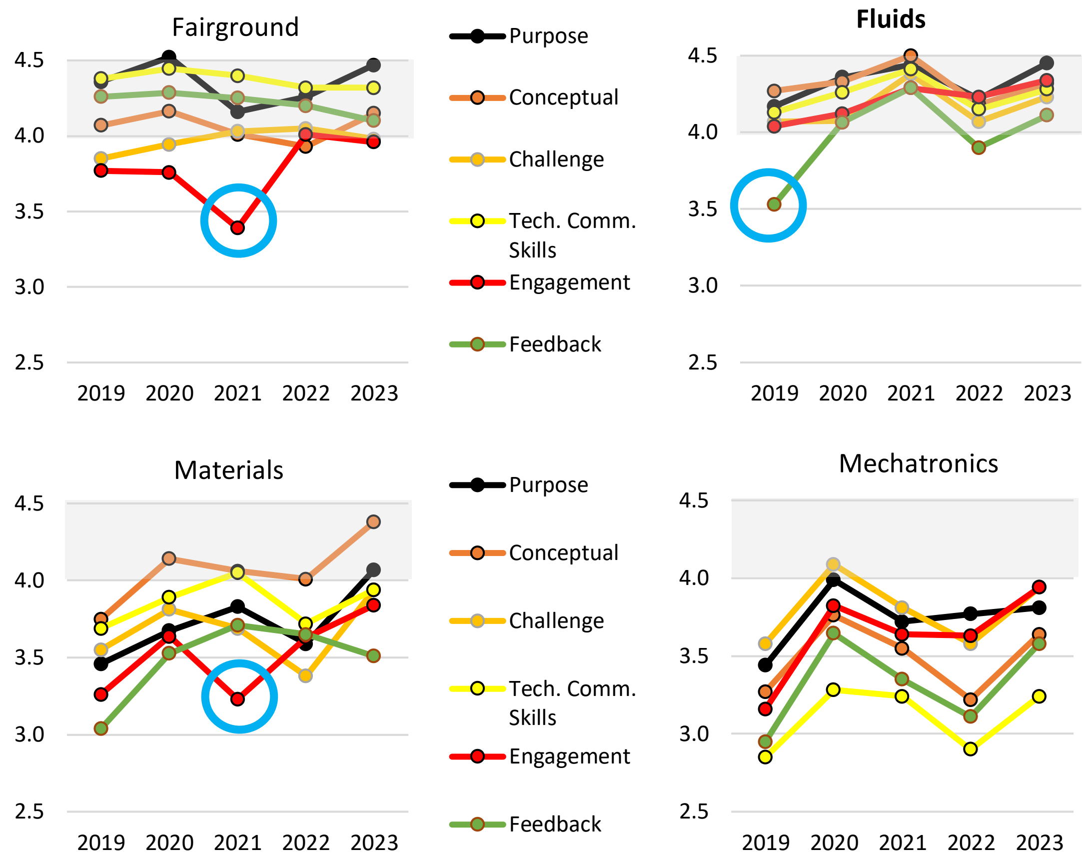

Fig 1. Plots of the mean (μ) in six categories, for four activities, over five years. The legend is the same for all plots. Cyan circles highlight cases for discussion.

scoring activities that were renewed before the survey began. The left column of Fig. 1 shows the activites that provided students with data during lockdown, while the right column shows activities for which the 'human robot' approach was used to acquire data (see Table 4). Further results are provided in Table 5 which includes the standard deviations.

4.1 Repeatability

Consider the 'Fairground' and 'Fluids' activities (top row of Fig. 1, top two rows of Table 5), which both scored consistently high ($\mu > 4$) over the five years. Their standard deviations are $\sigma < 0.15$ in all categories – indicated by green highlights in Table 5 – except two cases, circled in cyan in Fig. 1 and highlighted cyan in Table 5, to be discussed later. The value $\sigma < 0.15$ is significant; for example, a difference $\Delta\mu > 0.5$ between activities or between years is common. Hence variation of the results for these activities is low enough for the survey to be useful in practice.

For the remaining three activities, the standard variation was higher, mostly $0.15 < \sigma < 0.3$. The survey is still useful for these cases, but with lower confidence.

4.2 Sensitivity to difference between activities

The variability for one activity across cohorts (σ), is significantly smaller than the differences in mean scores ($\Delta\mu$) between activities. Perhaps the most obvious result

Table 5: Mean and standard deviation, $\mu \pm \sigma$, for the six consistent questions. Highlights: green: $\sigma < 0.15$, yellow: $\sigma < 0.3$, grey: $\sigma > 0.3$, cyan: notable cases.

	Purpose	Conceptual	Challenge	Tech. Comm. Skills	Engagement	Feedback	μ_2
Fluids	4.3 ± 0.13	4.3 ± 0.12	4.2 ± 0.14	4.3 ± 0.11	4.2 ± 0.12	4.0 ± 0.29	4.2 ± 0.1
Fairg'nd	4.4 ± 0.15	4.1 ± 0.10	4.0 ± 0.08	4.4 ± 0.05	3.8 ± 0.24	4.2 ± 0.07	4.1 ± 0.1
M'tronics	3.8 ± 0.20	3.5 ± 0.24	3.8 ± 0.22	3.1 ± 0.21	3.6 ± 0.30	3.3 ± 0.30	3.8 ± 0.3
Materials	3.7 ± 0.24	4.1 ± 0.23	3.7 ± 0.22	3.9 ± 0.15	3.5 ± 0.27	3.5 ± 0.26	3.6 ± 0.2
Thermo	3.5 ± 0.33	3.8 ± 0.14	3.8 ± 0.18	3.9 ± 0.19	3.2 ± 0.13	3.3 ± 0.10	3.5 ± 0.2

to make this point is for 'Tech comm skills' in yellow in Fig. 1 and the fourth column in Table 5. The mean for the Mechatronics lab, $\mu = 3.1 \pm 0.2$ is at least four standard deviations lower than the lowest scoring of the other activities. This reflects the fact that there is no technical communication in the mechatronics activity – it is a 'build and complete' activity with no assessed report/presentation, while the other four activities have an assessed technical communication. This result validates sensing differences in student experience between activities.

4.3 Validating interventions

The Fluids activity was revised for 2019. The survey indicated that the revision was successful except for feedback, identified in cyan in Fig 1 and Table 5. An intervention was implemented in the following years: feedback sessions between student and marker were scheduled after written feedback had been provided. This practice was copied from the Fairground activity, and the feedback score for the Fluids activity subsequently increased and remained high. The increase of $\Delta\mu = 0.50$ was $> 3\sigma$ in the following four years, which validates the intervention.

A second intervention was in activities that were adapted during lockdown – see Table 4. The left column of Fig. 1 shows activities where data was provided *a priori* to students. Significant drops ($\Delta\mu \approx 0.4$) in engagement (red line) with are evident, and are identified in Fig. 1, left column, by cyan circles. The right column of Fig. 1 shows where a 'human robot' was used to give students agency and interactively gather data. In those cases there is no drop in engagement. The survey provides evidence that a 'human robot' approach was more engaging that providing the data.

The Materials and Thermodynamics labs were subject to many smaller interventions over the years, which may explain the large variations. The Mechatronics lab was essentially the same over five years, so the larger variations for that activity are harder to explain.

5 DISCUSSION

Three aspects of the work presented are discussed here in more detail. Firstly, an interpretation of the results and some clarifications on their meaning. Secondly, a discussion of the validity and limitations of the survey. Finally, some 'use cases' where the results have had an impact on practice.

5.1 Interpreting the results

The relatively low standard deviation ($\sigma < 0.15$) for the two high scoring and consistently delivered activities gives us confidence to attribute larger changes, for example $\Delta\mu > 0.5$, to a change in the student experience. We can in turn, through our wider knowledge of the activities, attribute interventions as causes.

The case of mechatronics illustrates that nuance is required in interpreting the survey. The activity was delivered consistently for five years. The standard deviation was higher ($0.2 < \sigma < 0.3$), but the data in Fig. 1 show that the relative scores of each dimension were consistent. The variation from year to year appears to be uniform (the same for each dimension). In this case, the magnitude of change required in the survey results, before making conclusions with high confidence, is higher. However, the use of relative changes, of a smaller, magnitude can be used in as an alternative metric, albeit with lower confidence.

For any of the survey results, we urge caution when interpreting them. For example the low score in mechatronics for technical communication skills reflects the intent of the teacher. The low score is not necessarily a negative outcome. With this caution in mind, teachers can confidently take action based on the survey results.

5.2 Other forms of validity

Four forms of validity are briefly mentioned here: face, content, criterion, and construct validity. We believe that the face validity of the survey is high because it was developed iteratively through practice and the results are used by practitioners. The content validity is subject to the limited number of questions, for example there are no questions on practical skills. The criterion validity is good in the sense that relative measures are strong, but there is no absolute measure of any of the dimensions. We have not formally considered how students interpret the questions on the survey, but the free text comments and focus groups, combined with our hands-on teaching experience, provide some confidence in this area.

The construct validity of the survey has not been proven statistically. There is evidence in the data that survey results distinguish adequately. Questions were removed when correlations were found. The cases of technical communication skills in Mechatronics, feedback in Fluids, and engagement during lockdown, all support the use of the survey with confidence. This confidence is useful in practice, but it is not a rigorous statistical analysis. The selection of questions is heuristic and would benefit from a more rigorous analysis. Such analysis, however, is likely beyond the scope of this practical survey covering many activities.

5.3 Impact on practice

We use the survey to identify areas where action is needed. We propose an action, identify resources needed to take the action, and indicate *a priori* what changes to the survey results would validate the intervention. We conduct this process as a team across thirteen activities, including the five reviewed in this paper, and another eight in the second year of the programme.

The clearest example of an impact on practice is on the top-right plot in Fig. 1, where a low score for feedback prompted a change to feedback practices and a subsequent, significant, and sustained improvement in the survey scores and follow-up focus groups.

Another example of impact on practice is when an academic member of staff expressed an intention to improve the documentation for an activity. In this case the author advised the staff member not to make the improvement, because the high quality videos they had recently created returned the highest score of any activity in the ‘documentation and guidance’ category – a score which has since been maintained. In this case the impact on practice was to save the opportunity cost of doing work that was unnecessary – despite being well-intentioned.

The final type of example is where staff have targeted an improvement in survey scores with a well intentioned intervention, but that the survey results do not validate the intervention, e.g. the change in score is too small to be significant, or may even be lower. These cases are complex and require deeper analysis than the current survey is capable of supporting. In those cases more detailed evaluation and reflection is required.

6 CONCLUSIONS

A survey containing nine standard questions was used for all laboratory activities across a degree programme. This paper summarised the results from five years of data across five different activities in the first year of an undergraduate mechanical engineering degree programme.

The survey can identify the differences in student experience between concurrent activities and between cohorts. Validated examples include whether technical communication skills improved; the quality of feedback; and the level of engagement. We use the survey in practice to identify areas that need improvement; to validate interventions; and to monitor continued high quality activities.

The strength of the work presented here is its application over five years, and across a programme covering multiple activities. The survey has evolved from practice, which gives it an authenticity and face valitiy, but also limits its construct validity. A statistical validation of the question choice would improve the construct validity.

We will continue to use the survey in coming years, and suggest its wider use across our institution. We would be happy to hear from anyone interested in collaborating on the use of the survey.

Thank you to Idris Mohammed for his assistance with the survey over the last five years.

ABSTRACT

The use of educational technologies that use elements of machine learning (ML) and artificial intelligence (AI) are becoming common across the engineering education terrain. With the wide adoption of generative AI based applications, this trend is only going to grow. Not only is the use of these technologies going to impact teaching, but engineering education research practices are as likely to be affected as well. From

[1] *A Johri*
johri@gmu.edu

data generation and analysis, to writing and presentation, all aspects of research will potentially be shaped. In this practice paper we discuss the ethical implications of the use of generative AI technologies on engineering teaching and engineering education research. We present a discussion of potential and futuristic concerns raised by the use of these technologies. We bring to the fore larger organizational and institutional issues and the need for a framework for responsible use of technology within engineering education. Finally, we engage with the current literature and popular writing on the topic to build an understanding of the issues with the potential to apply them in teaching and research practices.

1 INTRODUCTION

The contemporary educational sector, including higher education institutions (HEIs), exists in a highly technological state. In addition to traditional applications such as Learning Management Systems (LMS), universities use videoconferencing, automated assessments, and increasingly, Machine Learning (ML) or more generally Artificial Intelligence (AI)-driven applications. From TurnItIn to Grammarly, these new technologies have found broad application including in engineering education. In addition, the data generated by these applications has lead to features that employ Learning Analytics (LA) and Educational Data Mining (EDM) for sensemaking.

The major difference between the newer technologies now in use for education and research and those used earlier, is the generation of data and capabilities that have been developed to analyze analyse and use that data. In recent times, the field of AI has entered a new era marked by remarkable advancements in generative AI applications. One notable example is ChatGPT (Dwivedi et al., 2023), which builds upon the power of Large Language Models (LLMs) (Qadir, 2023). By harnessing the wealth of textual data accessible on the internet, these applications create models with the ability to predict highly probable completions for any given text. As a result, they exhibit language generation and conversational capabilities that closely emulate human-like interactions.

While these technologies have opened up numerous promising applications that align with educational and research objectives of engineering, it is essential for us as a community to address important questions arising from their rapid and uncritical adoption. This collective effort is crucial to ensure their responsible use and mitigate potential concerns. Especially as engineering educators preparing the next generation, we have a moral obligation to think deeply about these issues and reflect on our use of technology across our own practices, as we prepare our students to practice in a world where these technologies exist (Johri et al., 2023; Johri, 2020).

2 ETHICAL CONCERNS

Emerging technologies provide a range of new affordances that we can use in educating future engineers. In deciding how these AI technologies should be employed in our teaching, there are a range of key ethical concerns that we must consider. Scholars in multiple communities, such as LA and EDM, have commented extensively on these issues (Kitto and Knight, 2019; Slade and Prinsloo, 2013; Tzimas and Demetriadis, 2021). Navigating these ethical issues is not always straightforward as often we face dilemmas of conflicting demands of values that we hold. For instance, the use of complex LLMs can improve our ability to make accurate predictions but they also reduce our ability to understand how they work (Whittlestone et al., 2019); the use of generative AI can result in impressive applications but may also result in the loss of jobs and deskilling of humans. In what follows, we discuss some ethical concerns surrounding generative AI and the use of automation in education.

2.1 Data privacy and consent

A fundamental concern with the use of new forms of digital technology is how they handle data – what data is collected, how is it stored and retrieved, where is it stored, and what kinds of consent provisions are available to users. The majority of education contexts where AI is deployed are systems and situations that are intrinsically linked to core operations of the university - situations where students are either not asked to consent, or where refusing consent would be impractical. Opting out of automated assessment is impossible; seeking explicit consent for data mining of historical data is similarly impractical.

Increasingly, developers of educational technology products tend to gather more data than what is functionally needed for potential future use and extensions. This has meant that data have been collected en masse with little regards to their actual use, and data can be repurposed for purposes different from their original intended use. Consequently, consent mechanisms are overreaching in what they ask of users; similar to the “I Agree” most of us click on while accessing most digital platforms – a consent that is in conflict with the GDPRs data minimisation principle.

2.2 Algorithmic bias

A related concern to data is how the data are analyzed analysed and used. Increasingly, systems use ML techniques to make sense of the data. To develop these algorithms, they have to be trained on datasets. These datasets are largely developed through data that are readily, conveniently, available and not necessarily represenative of a specific issue. As an example, to develop facial recognition algorithms, a large number of faces have to be fed to the algorithm and then labelled as “face” so that the algorithm knows it is a face. If the data that is used to do this is largely white faces, as has historically been the case, then the algorithm performs poorly on other skin tones. Thus, algorithms inherently develop a bias and the more they are used the more they get “trained” to make a mistake unless it is intentionally corrected. The act of identifying previous implicit biases can itself be problematic. How should we respond to the discovery that an accurate model of our current practice identifies a clear practice of bias? How should we treat a colleague who our algorithm has identified to be biased, but whose bias has only been made visible through their voluntary consent to participate in our modelling study?

2.3 Transparency and opacity

How does one know that the algorithm is biased? Detecting algorithmic bias often occurs unintentionally when it demonstrates flawed behavior during actual implementation. Testing algorithms can be challenging since they are essentially "black boxes" kept proprietary by their developers. Additionally, with the rise of deep learning and LLMs, even the creators may lack full awareness of the inner workings and steps involved in generating outputs. The complexity of training neural network-based algorithms makes understanding their functionality nearly impossible. Balancing the need to protect privacy and intellectual property presents difficulties in disclosing algorithmic workings and the underlying training data. This issue is particularly pronounced when dealing with student data, which is regarded as confidential in Europe and often enjoys federal protection in the United States, making it challenging to access the data used to develop a technology. There are several avenues being pursued in this area, especially the subfield of Explainable AI (XAI), where scholars have developed methods to make the use of AI more transparent across the application lifecycle (Dengel, et al., 2021; Doran, et al., 2018).

2.4 Equity and access

ML based technologies for learning can potentially treat all users as equal, ensuring accessibility that is fair to all. They can also things more equitable by prodiving services to those who need it most. Furthermore, they can support scaling up for services at a faster pace than is possible through purely human resources. Given the differences in learning opportunities, prior knowledge, and different backgrounds of students, this is a high barrier for many technologies to meet. For instance, how do you ensure that everyone understands their rights and consents with full knowledge if their technological literacy is different? There are also students that need accommodation due to different reasons and neurodiverse individuals who should also have equal access. Although technology use seems universal, many nuances that need to be worked out to ensure equity in the use of technologies.

2.5 Individual versus community approach to education and learning

Increasing personalisation of services and information may bring economic and individual benefits, but risks creating or furthering divisions and undermining community solidarity. The attractiveness of AI systems is that they can effectively automate the most common tasks; but this risks introducing a “tyranny of the majority”, where the needs of minorities in the long tail are overlooked because they are difficult to automate. The most effective and accurate algorithms, in terms of their predictive power or accuracy, may be based on complex methods (such as deep learning). The inner workings of such algorithms might not be fully transparent to developers and may result in systemic discrimination against a minority class even if it is on average accurate. As argued by Engelbart (1962), complex problems (commonly referred to as "wicked problems" nowadays, such as addressing hunger, containing terrorism, or fostering rapid economic growth) cannot be solved through technology alone (no matter how advanced it may be). The full potential lies in human-computer symbiosis where technologies like generative AI and algorithms are utilied to augment the collaborative efforts of human communities.

2.6 Human-Centered Learning and Human-in-the-Loop Learning

Human learning is not merely a technological challenge. It is important to temper our expectations and recall our past underwhelming experiences with supposedly revolutionary technologies, as emphasised by Langdon Winner (2009). Education is about the humans involved and should remain human-centered. It must also be remembered that education involves attaining proficiency through practice and mastery through understanding, which cannot be automatized automatised or rushed and attained instantaneously. We will do well to benefit from previous systematic thinking on human augmentation so that human capacities and capabilities are effectively augmented to solve the problems humanity face (Johri, 2022).

The operational intention of many ML approaches is that they should be decision support systems, making recommendations to humans who actually make the decisions. Over time, however, there is the risk that this will drift – particularly if the models turn out to be very effective. If a model only rarely turns out false negatives (for instance, failing an assignment it should have passed), for how long will we commit the resources to check all of the negatives for the false one? This question is particularly relevant if false negatives result from implicit bias in our models.

2.7 Speed of innovation versus equality, safety, credibility and sustainability

The rise of AI, and generative AI specifically, has given rise to an influx of funding support for innovation from both the private sector and governments. Across the world, new companies and industries are being formed, leading to new products. Although this innovation is necessary for using AI beneficially, this arms race of sorts is also likely to lead to sustainability and climate change challenges, as well as issues of inequality if this continues to be a winner-takes-all battle. More resources are likely to be put into technologies that will benefit a few as opposed to those with lower profitability but broader impact.

Pursuing technological progress at breakneck speed may compromise the safety, robustness, and reliability of these developments. While adapting to changing times is desirable, universities have historically been slow to evolve. The credibility of universities rests on thorough quality assurance processes, which often struggle to keep up with the latest technological advancements. While an ill-advised response could be to outright ban such technologies, this approach merely introduces enforcement and compliance issues, while further distancing academic practices from the eventual professional practices that are inevitably on the horizon.

2.8 Efficiency vs. effectiveness

AI offers great promise in automating and streamlining the common and recurring aspects of the learning experience. However, in the pursuit of efficiency, we risk neglecting the less common but equally important elements. Although AI is proficient in addressing the majority of learning features, it may encounter difficulties when confronted with exceptional cases and outliers. While we can identify the primary feedback provided by humans to students and create automated systems to deliver it on a large scale, there is a danger of disregarding the valuable feedback that falls outside the common patterns. We must consider how human-machine augmentation can be best practiced so that it does not sacrifice human ingenuity in search for efficiency (Dengel, Devillers, and Schaal, 2021). Having invested in automating this feedback, we may be tempted to reuse the same model in subsequent years without updating it to account for contextual changes, evolving theories, and the distinct learning profiles of each year's student cohort. While there is immense potential for more efficient resource allocation, we must ask ourselves if we can still uphold our graduate standards if we solely focus on automatable outcomes. Moreover, it is essential to consider whether the resources freed up by automation will be redirected to address non-automatable elements in teaching or instead diverted to research, central administration, or budget cuts.

2.9 The dignity of academic work

Technological determinism often dictates that we machines to the extent possible; however, much of higher education has always been experienced, and valued, as an artisanal human process (Crawford, 2009). Increasing automation and quantification could make lives more convenient, but risks undermining those unquantifiable values and skills that constitute human dignity and individuality. This is especially applicable to teaching, which is a personal profession and in most cases a respected profession. The use of technology to automate educational practices risks making the work less dignified devoid of purpose.

3 FRAMEWORKS AND CHECKLISTS

The range of issues highlighted in the previous section motivates systemic approaches to the design and development of AI systems in engineering education. In this section, we will present two existing frameworks, DELICATE and RESPACT, which are relevant for operationalizing AI in engineering education. We then discuss unique challenges posed by generative AI which future frameworks should consider.

3.1 DELICATE

The DELICATE checklist (Drachsler and Greller 2016) was developed as an instrument for educational institutions to engage in ethics and privacy discussions around the use of educational technologies that use Learning Analytics (LA). The authors argue that there are ways to design privacy protections and consent mechanisms so that all stakeholders are benefitted.The checklist consists of the following elements to guide the use of LA applications:

1) ***D****etermination*: Why do you want to apply Learning Analytics;
2) ***E****xplain*: Be open about your intentions and objectives;
3) ***L****egitimate*: Why you are allowed to have the data;
4) ***I****nvolve*: Involve all stakeholders and the data subjects;
5) ***C****onsent*: Make a contract with the data subjects;

6) ***A**nonymise*: Make the individual nonretrievable;
7) ***T**echnical*: Procedures to guarantee privacy; and,
8) ***E**xternal*: If you work with external providers.

Overall, the checklist contains guidance on paying attention to the value of LA and the rights of participants, ensuring that there is transparency about the use of LA and that users give consent openly and willingly. There is also an emphasis on data anonymization and institutional guidance for adopting clear and transparent obligations with any external agencies involved (Drachsler and Greller 2016).

3.2 RESPACT

Another related framework developed on the basis of review of the literature and empirical work (Johri and Hingle, *forthcoming*; Johri and Hingle, 2023) is RESPACT, with applications specifically for educational technologies that use ML/AI and are implemented in an HEI context. The framework consists of the following elements:

1) ***R**esponsive*: The technology needs to be *responsive* to user needs and work *responsibly*. Often the implementation of technologies is done without consideration of whether it fills a need and is usable.
2) ***E**thical*. It is imperative that organizations use some set of *ethical guidelines* for technology procurement and implementation. Institutions may already have access to guidelines for protecting student data that can be expanded for this.
3) ***S**ecure*. The *security* of data is paramount in any technology implementation. With increasing attacks on systems and stolen data becoming common it is vital that insitutions work sincerely towards securing their infrastructure.
4) ***P**rivate*. Privacy is one of the most contentious aspects of technology use and implementation. For educational institutions, it is essential that they view privacy contextually and are guided not just by the law but also by their ethos.
5) ***A**ccountable*. Accountability is another consideration as the misuse of data or of technology has to be righted, and the insitution needs to ensure compliance as well as working within appropriate frameworks.
6) ***C**onsent-Driven*. Consent needs to go beyond simply informed consent to all the involved parties. Consent should extend toward differential schema, so that diverse users can agree to the terms based on their preference.
7) ***T**ransparent*. As technologies get more complex, it is hard for a user to understand all the integrated functions and services and the flow of information or data through the overall system. Transparency is essential for explainability and, consequently, for trust; a user will trust more what they understands better.

Overall, the RESPACT framework, which comes out of empirical work on video-based monitoring of exams (Johri and Hingle, 2023), provides a institutional level set of guidelines for technology use and implementation. While it recognizes that user protection is essential, it also emphasizes institutional imperative of data security and responsiveness to user needs.

Through the exploration of the DELICATE and RESPACT frameworks, we have identified key ethical considerations for the use of AI in engineering education. Both these frameworks stress the importance of transparency, accountability, and the involvement of all stakeholders. They also emphasize the need for consent-driven approaches, addressing privacy concerns, and ensuring the security of data.

3.3 Applicability of these frameworks for Generative AI

While the frameworks listed above are generally applicable to a range of edtech and AI scenarios, generative AI poses some unique challenges, which requires special attention, demanding extension of these frameworks in future work (Kasneci et al., 2023; Weidinger et al., 2021). Some of these new challenges are outlined next:

a) ***Avoiding AI-aided plagiarism***: How to cope with situations where ready-made answers become available to students, who can simply copy-paste them and not disclose such AI-generated plagiarism?
b) ***Avoiding deskilling***: How to cope with deskilling that emerges as students are not required to engage in learning and provided directed answers?
c) ***Enhancement of human capacity***: How can we ensure that the use of generative AI augments human capabilities and does not atrophy them?
d) ***Fair use of AI generated content (AIGC) and AI agents***: Is it ever fair to use AIGC without full disclosure? Is it ethical to leave decision making in the hands of algorithms? Who is liable in case of an inappropriate response?
e) ***Equity and accessibility***: How to ensure that everyone can equitably access the benefits of generative AI and tools do not exacerbate inequality?

Future frameworks should look at the dangers of automation in the field of engineering education and attempt to keep engineering education human-centered and avoid what Brynjolfsson (2022) calls the “Turing Trap” (the focus on automation and artificial intelligence rather than on human intelligence augmentation).

4 CONCLUSIONS

The widespread adoption of generative AI and automation within engineering education raises significant ethical concerns that cannot be ignored. We have highlighted some new unique challenges posed by generative AI such as AI-aided plagiarism, deskilling, the imperative for human augmentation and capacity enhancement, fair use of AI-generated content, and equity and accessibility. These concerns highlight the need for the development of comprehensive ethical AI frameworks that address the unique challenges posed by generative AI. As generative AI technologies become more integrated into education, it is crucial to assess both their short-term benefits and long-term consequences for teaching and learning. The scalability and complexity of these applications require a deliberate effort within the educational community to minimize harm and promote responsible use. Extending existing ethical guidelines to meet new challenges posed by generative AI and emphasizing transparency, accountability, privacy, and human-centeredness, we can mitigate the risks and maximize the positive impact of generative AI in engineering education.

ABSTRACT

This paper presents the results of surveys conducted among students and teachers / mentors in Nepal, Bhutan, and India, regarding the impact of implementing Problem-based learning (PBL) methodology in engineering and multidisciplinary projects. The surveys were carried out under the Erasmus+ funded project, "Strengthening Problem-based learning in South Asian Universities" (PBL South Asia). The project aimed to address the issues of education quality, employability, and sustainable development in the region by enhancing students' practical experience, communication skills, teamwork abilities, as well as academic knowledge through PBL-adapted courses. As a result, South Asian higher education institutions have implemented PBL courses in their curriculum.

The surveys were designed to evaluate how specific competences or learning outcomes were perceived by different stakeholder groups, e.g., which learning outcomes were expected to be achieved by the faculty, and whether they were achieved by students. Several methods were used for the assessment – open questions with tracking the keywords that the respondents use, as well as "EntreComp" framework which looks into how students assess their abilities to be curious and open, think sustainably, behave ethically, and cope with uncertainty and ambiguity.

Results of the survey showed that student participants have identified teamwork, communication and presentation skills as those most associated with PBL methodology. Among the self-assessed improvement in abilities, students have indicated their increased abilities to assess the needs of different stakeholders, combining different contexts, setting up strategies.

1 INTRODUCTION

1.1 PBL methodology in engineering

The role of practicing engineers in promoting sustainability is vital, as their work is closely tied to societal progress. In recent decades, there has been a growing interest in pedagogical approaches that equip students with the competences required to make effective decisions in a rapidly changing world. These approaches frequently link the United Nations' Sustainable Development Goals with learning outcomes and employ constructivist and student-centered methods to contextualize sustainability issues within local, disciplinary, and professional contexts (UNESCO 2017, Rajabifard et. al. 2021) Problem-based learning (PBL) is one of such approaches that has gained attention as a pedagogical strategy capable of providing the necessary learning outcomes to foster a sustainable society (Thomas 2009).

PBL has been widely adopted in engineering education for its potential in developing students' professional skills, motivation and subsequently, their academic performance (Duch et. al. 2001, Acharya et. al. 2021, Acharya et. al. 2021). By the virtue of this learner-centered approach (Savery 2015), engineering students are given opportunities to actively engage with open-ended challenges (Torp and Sage 2002, Hmelo-Silver 2004) through understanding, finding, learning and applying theories in a self-directed and multidisciplinary way. In terms of professional skills, the PBL approach especially facilitates the development of capabilities needed to work in diverse disciplinary contexts requiring collaborative knowledge construction, which is needed both in engineering professional practice and addressing complex challenges (Torp and Sage 2002, Kolmos and Graaff 2015). These skills are essential for future careers as new and upcoming technologies and tools exceedingly create demand for creative and competent engineers capable of solving complex challenges of the society.

Although PBL has gained recognition as an effective teaching method in engineering education, empirical research on its implementation has predominantly been focused on Western contexts. There has been limited research on PBL in regions where traditional, teacher-centered approaches are still prevalent. Additionally, there are few examples of PBL's practical implementation and effectiveness in cross-institutional contexts, particularly in international collaborations. A study on South Asian universities found that present undergraduate engineering education offered is didactic, content-heavy, lacking adequate practical experience and knowledge of real-world sustainability issues and impact, as well as industry-ready competences (Acharya et. al. 2021). The current undergraduate engineering education scenario – at the regional and local level, through secondary and primary research, highlights the policies and challenges in the face of implementation of the same, due to varied structure of autonomy, as well as resource availability. These are big constraints, especially in South Asian countries with similar institutional contexts such as India, Nepal and Bhutan. The engineering education and curriculum development is usually overseen by the national level body on technical education (e.g. All India Council for Technical Education – AICTE in India; Nepal Engineering Council – NEC). The engineering courses are offered on university campuses or in affiliated colleges. While the independent university campuses enjoy a relatively greater freedom in designing and execution of curriculum for engineering courses (based on broad guidelines from the national bodies), the affiliated colleges are constrained to use the syllabus prescribed by the university to which they are affiliated. Furthermore, the evaluation schemes vary differently between deemed universities. The university-based engineering courses have greater flexibility in assessment schemes, whereas the affiliated colleges are more restricted to follow the guidelines for the universities. The assessment is usually done by a common exam across all affiliated colleges within a university. Thus, the teaching in colleges are geared toward preparing the students for these common examinations, rather than preparing them in solving real-life, 'wicked' problems.

Against this background, this paper reports the impact of a cross-institutional and multidisciplinary PBL methodology on students, teachers and faculty from South Asian and European HEIs.

1.2 Case study: PBL South Asia project

The PBL South Asia project, a joint initiative among ten universities from India, Nepal, Bhutan, Finland, the Netherlands, and Lithuania, was co-funded by the Erasmus+ Programme and led by Aalto University, Finland. The project ran from 15.11.2018 to 14.11.2022 aiming to develop curricula and teaching competence in PBL for global sustainability themes, particularly in the technical field, to enhance critical thinking, innovation capacity, professional skills, and employability among students in intercultural and regional contexts in South Asia. During the project, six partner HEIs from Nepal, India, and Bhutan developed and implemented PBL-based curricula. All HEIs engaged in co-creation of educational content, practices and intercultural engagement around PBL methods application in courses offered to diploma, undergraduate, and graduate students among partner HEIs. The project developed practical teaching competences, transitioning from traditional to student-led learning in the region. It facilitated iterative student-led challenges and interdisciplinary group work, independently and as a component of newly adapted PBL curricula, bridging teacher training in action with peer teaching activities among the consortium members. This approach also encouraged increased engagement between academia and local societal and innovation ecosystem partners to address complex local and global sustainability challenges, while building skills and knowledge among participating students, mentors, and course coordinators.

PBL is no new invention, yet its application in multicultural, multidisciplinary and deeply heterogeneous HEI settings with advanced and beginner levels of PBL adoption is an unusual approach as implemented in the project. It called for a culturally adjusted reinterpretation of normative sustainability agendas, an encounter of entirely different realms of competence, a format in which teachers take the supportive role in facilitation and students take the lead role in learning, balancing and navigating hierarchies and cultural barriers, to develop novel international practices for inclusive PBL education. Project HEIs were organised into three groups: European Programme HEIs, Nepal and Bhutan HEIs aiming for PBL integration and Indian HEIs aiming for best practices development in regional applications of PBL education and teacher training. Activities were mostly based in South Asia, due to the assumption that educational content development needs to take place in the context where it will be rolled out, ensuring actionable changes and locally appropriate modalities. It was also evident that the experienced universities did not have advanced knowledge of teaching circumstances at South Asian HEIs.

Despite serious disruptions to project implementation by the Covid-19 pandemic, the main results and overall impact were achieved. The results include but are not limited to, the introduction of PBL via adapted curricula in Nepal and Bhutan, best practices and teacher training development in India and Europe, a series of international and local student projects, significant institutional engagement and dissemination at consortium HEIs on PBL education, an internationally cocreated MOOC course and modules, follow-up projects and networks.

2 METHODOLOGY

The PBL courses were created or updated in South Asian partner HEIs. Main competences that the new and updated courses are addressing: transversal, behavioural skills, technical, academic, scientific and research skills, linguistic competences, group work skills, interpersonal skills, and learning by doing in the real-world scenario skills.

Before the PBL South Asia project, most of the HEI's in South Asia did not offer PBL courses and most of the teachers/mentors also were not trained in PBL methods. In order to assess the benefits of the PBL questionnaires were designed for students, mentors/teachers, and faculty to be filled in both before and after the PBL courses and distributed online. The surveys were designed to evaluate how specific competences or learning outcomes were perceived by different stakeholder groups, e.g., which learning outcomes were expected to be achieved by the faculty, and whether they were achieved by students. The surveys also investigated PBL practices – the methods used in the courses, the organisation of the teaching/learning process, the logistics, management change, etc. The methodology of questionnaires crosscheck is presented in Fig.1.

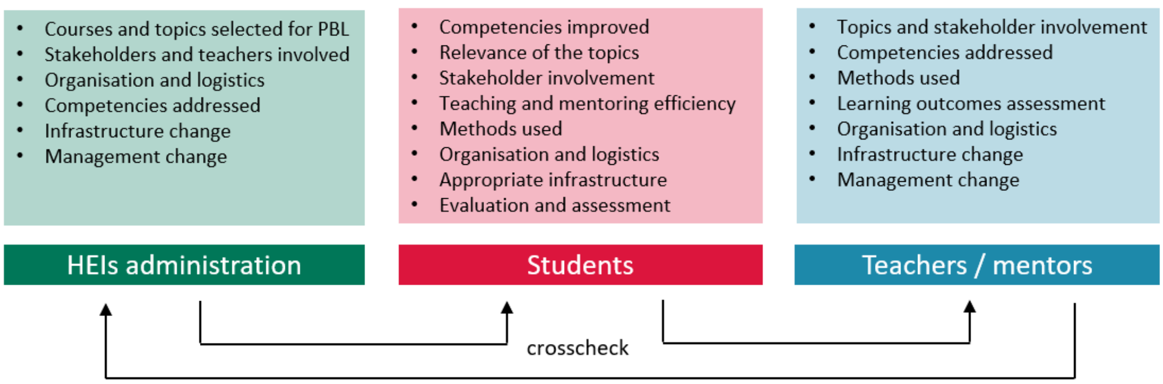

Fig. 1. The PBL SA Methodology of Questionnaires Crosscheck

Two sets of questions were included in the survey – the first set of questions was looking into the overall satisfaction with the PBL courses and understanding of PBL methodology, including the open questions which were used for keyword extraction, as well as collecting the data on the competences increased. The second set of questions was based on the “EntreComp” framework (McCallum et. al. 2020) and investigated behavioural patterns and skills, namely – how students assess their abilities to be curious and open, think sustainably, behave ethically, and cope with uncertainty and ambiguity. The feedback gathered from students’ questionnaires is collected from the updated courses, and thus also reflects the experiences students have had in these various local or international real-life case studies.

A selection of the EntreComp framework was used for the PBL courses evaluation as there is an overlap of competences being addressed in PBL education and entrepreneurship education. The EntreComp framework is a tool designed by a consortium of researchers and funded by the European Union to support the development and understanding of entrepreneurship competences. The framework includes a range of fifteen entrepreneurship-related competences, divided into three main categories: ‘Ideas and Opportunities’, ‘Resources’, and ‘Into Action’. It is designed to be used in entrepreneurship education programs to help students develop their entrepreneurial skills and knowledge.

The first category, Ideas and Opportunities, includes five competences that relate to the identification and evaluation of business ideas. The competences for this category are: Creative thinking, Opportunity identification, Vision, Valuing ideas and taking calculated risks, and Ethical and sustainable thinking. The second category, Resources, includes six competences that relate to the management and utilization of resources to create and run a successful business. These competences are: Mobilizing resources, Financial and economic literacy, Taking the initiative, Planning and management, Coping with uncertainty, and Learning through experience. The third category, Into Action, includes four competences that relate to the implementation of business ideas and the management of a growing enterprise. These competences are: Mobilizing others, Communication and persuasion, Self-awareness and self-efficacy, and Initiative and perseverance.

The total number of students’ responses received before the course was 75. However, approximately 25% of students did not complete the survey after the courses. Nevertheless, this is quite typical in the academic setting, and the participants were only invited to submit their responses twice, in order to avoid random or careless responses just for the sake of responding. The number of mentors who filled in the survey before and after the PBL course was 15 and 14 respectively.

3 RESULTS

Before integrating PBL into South Asian HEIs, questionnaires were given to the administrative staff / managers of South Asian HEIs. The objective was to identify the expectations held by the HEIs regarding the skills and competences that students would enhance through the adoption of PBL. Since only one response per institution was collected for the survey, the detailed findings are not presented in this paper. However, there was a consensus among the respondents, and the expectations of the HEIs revolved around embracing new pedagogical approaches, fostering active learning, producing industry-ready graduates, enhancing problem-solving abilities, improving communication skills, and developing a better understanding of the complex and multidisciplinary aspects of their respective professions.

The results of the students and teachers / mentors responses are presented in Fig. 2.

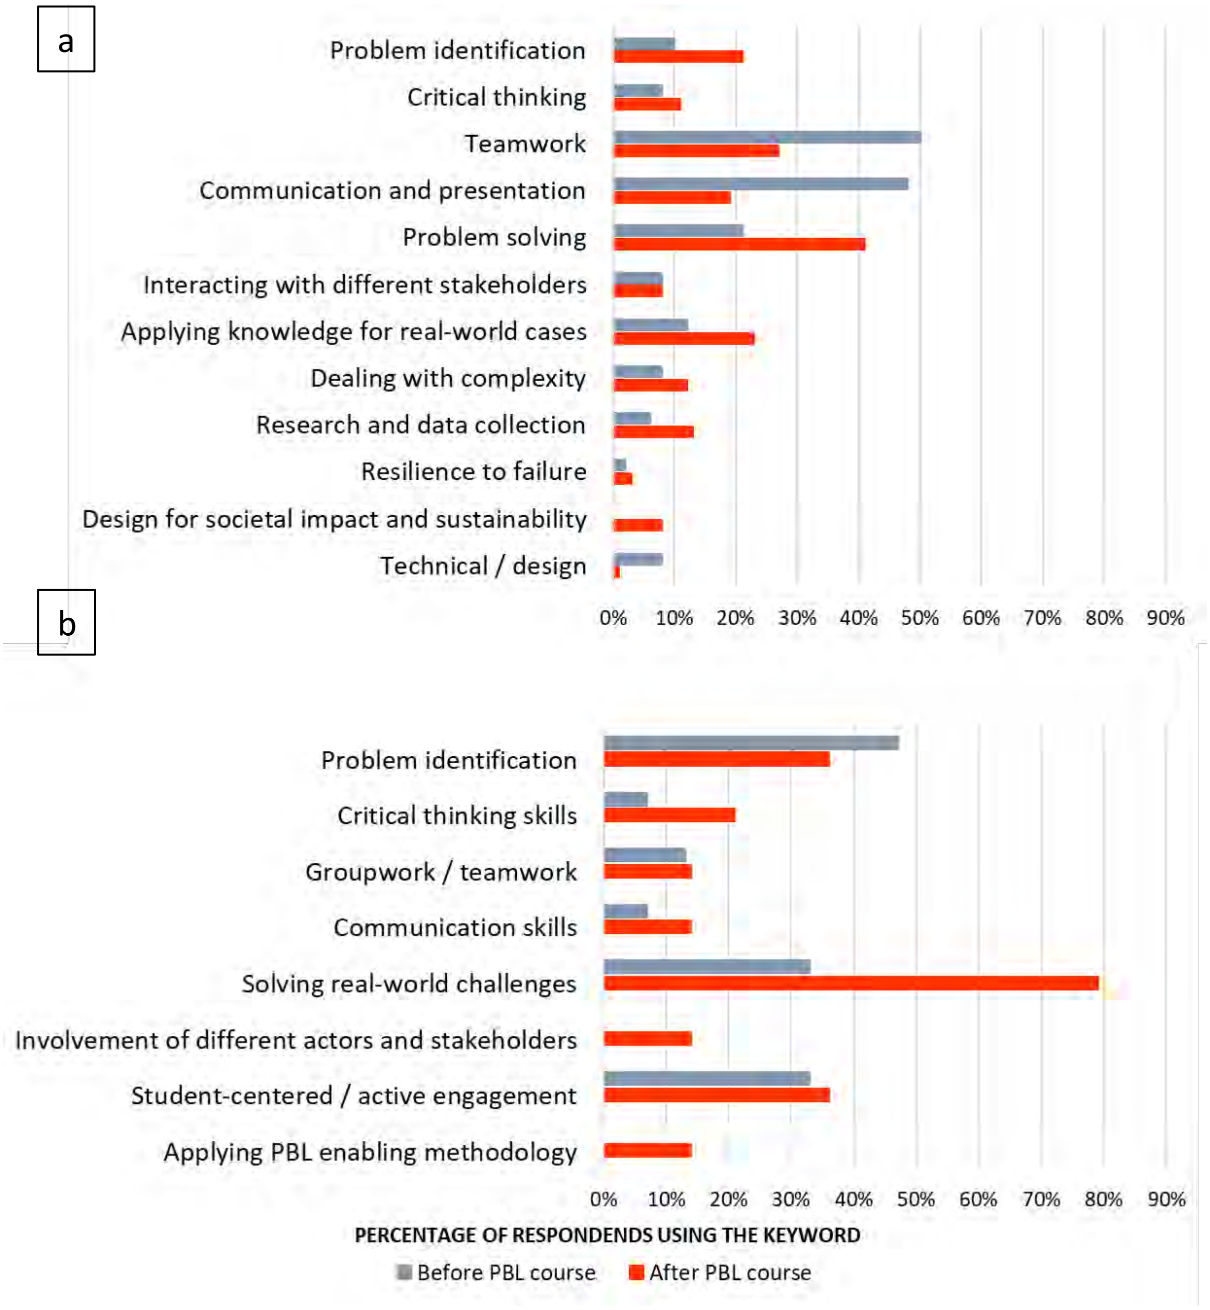

Fig. 2. The appearance of selected keywords in the responses of students (a) and teachers / mentors (b)

The results of the students' responses showed that students perceived the concept of PBL differently before and after the course. As it was mentioned before, open questions were provided for students, where they could write their associations and statements. The chosen keywords indicated how students' perceptions changed before and after the PBL courses. Keywords analysis showed that most of the students extracted these competences obtained after PBL courses: improved technical / design skills; improved teamwork skills; developed skills in communicating with stakeholders; developed communication and presentation skills; built confidence in speaking and listening; improved leadership skills. Keywords analysis also showed that PBL courses had a significant impact on the competences of students.

Analysis of students' responses to the "EntreComp" framework survey showed that students have increased the ability to identify challenges after the PBL courses; they also improved their teamwork skills and their ability to deal with complexity. Keywords analysis and responses to the "EntreComp" framework survey demonstrated that the PBL methodology that was used in the new courses had a positive impact.

Based on the results of the received students' responses, it can be observed that HEIs expectations, which were raised before the PBL courses, have been implemented. Students improved their communication skills along with teamwork and leadership skills. However, it is noteworthy that, after PBL course, students mentioned "Teamwork", "Communication and presentation" keywords less frequently. Instead, they emphasized other aspects of PBL, such as "Problem identification and solving" and "Real-world cases." This indicates that students initially placed more emphasis on the process of PBL prior to undertaking the course, while certain associations became stronger after completing the course, aligning with the outcomes and experiences gained.

A similar analysis was also done with teachers/mentors when the keywords most commonly encountered in their responses were selected, and how their perception changed after PBL courses. Analysis of the appearance of selected keywords in the responses of teachers/mentors showed that the most common keyword appearance was: solving real-world challenges; applying methodology and involvement of different stakeholders; critical thinking skills; communication skills.

The survey showed that courses had a significant impact on the competences in both professional and personal fields. It can be seen that teachers/mentors are able to apply PBL methodology, involve different stakeholders, etc. It shows that after PBL courses teachers and mentors gained the ability to apply new teaching methodologies.

The results of both students' and teachers'/mentors' analysis showed that most of the expectations raised before the PBL courses were achieved.

4 SUMMARY AND ACKNOWLEDGMENTS

Higher education institutions expect new pedagogical approaches and a shift towards active learning to produce industry-ready graduates with advanced problem-solving, communication, and multidisciplinary skills. Students associate PBL courses with improved teamwork, technical, design, communication, and presentation skills. Meanwhile, teachers/mentors emphasize the importance of involving stakeholders, promoting active engagement, and developing real-world problem-solving abilities through appropriate methodologies.

Moreover, the success of PBL integration initiatives relies heavily on continuous teacher support, motivation and networking with other universities in the region. The PBL South Asia project addresses this by creating a PBL network and online course for PBL applications in solving sustainability challenges, which serve as resources for teachers and students alike.

This publication is part of the 'Strengthening Problem-based Learning in South Asian Universities' (PBL South Asia) project, co-funded by the Erasmus + programme of the European Union*. ABSTRACT

International Cooperation Framework for Next Generation Engineering Students (NextGEng) is an Erasmus+ Cooperation partnership in higher education project which started at the beginning of October 2022 and will end at the end of September 2025. In this project, there are six full partners who are participating in all project's activities: Technical University of Cluj Napoca (main partner) and Robert Bosch SRL from Romania; Jamk University of Applied Sciences and Valmet Technologies Oyj from Finland; University of Jaen and Sensory Integration and Robotics from Spain. This project aims to develop an international cooperation framework that promotes international team-teaching aligned with the European Education Area 2025 and labour market needs, including actions to support collaborative, international and experiential learning in engineering. To achieve that end, NextGEng activities are based on three lines of action: a tailored training process for teachers, an international team-teaching pilot program and cases for experiential learning. This paper describes the aims and main activities of NextGEng, details of three lines of action, and achieved results during the first project year.

1 INTRODUCTION

One of the main objectives of higher education is to provide its graduates with the skills needed to succeed in the labour market. This mission is especially important in the context of today's innovation-driven, skills-based and globalized economies. To produce graduates with strong technical and professional competencies, Higher Education Institutions (HEIs) are facing many challenges. They have to develop new teaching methods that motivate students to learn and become highly qualified graduates with the competencies to work in new kinds of jobs.

Additionally, the last pandemic has meant a sudden transformation in teaching and learning processes, especially in terms of digitalization. Under such circumstances, HEIs have had to adapt their teaching and assessment methodologies in a short time. Transitioning from traditional face-to-face learning pedagogies to virtual ones requires time, expertise, resources, and motivation. The speed with which changes have taken place has affected the learning process and some difficulties have arisen for students to follow lectures or to organize their tasks. Digitalization has fostered the implementation of virtual learning methodologies, which are needed to upgrade the existing materials and to create collaborative work with an international approach (Vincent-Lancrin, S., et al. 2019) and (Visvizi, A., et al. 2018).

New challenges are especially demanding in engineering degrees, where the theoretical complexity and the practical work at the laboratory to train applied skills, require adequate guidance of students from teachers, and the creation of quality learning material. Besides, the industry is one of the most innovative, changing labor agents, and therefore it is crucial to train and prepare future engineers for successful professional development. Based on the above-mentioned, it seems necessary to rethink the teaching methodologies to produce upgraded courses, featuring a student-centered approach and in cooperation with other international institutions and companies. In that sense, the European Commission is working in this direction through the creation of the European Education Area (EEA). Some of the main objectives are related to the improvement of the quality of education from a collaborative perspective, which considers digital transformation and inclusion.

HEI and company partners of the NextGEng project have cooperated for many years, so they know each other's skills and strengths and they have now a good possibility to deepen cooperation. HEI partners have already earlier done successful cooperation and reached good pedagogical outputs and results (Kakko, A. 2016), (Kakko, A., Matilainen, J., Satorres Martínez, S. 2017), (Satorres Martínez, S., et al. 2019), (Torres Jiménez, E., et al. 2019) and (Satorres Martínez, S., et al. 2020). This means that the International Cooperation Framework for Next Generation Engineering Students (NextGEng, www.nextgeng.eu) project is a safe and feasible opportunity to foster the transformation of engineering degrees in line with the aims of the EEA. This project for its part helps to adapt these studies to the changing environment, which demands students to have interdisciplinary, inclusive, cooperative and digital capacities, to quickly adapt to the labor market.

2 BASIC INFORMATION ABOUT THE NEXTGENG PROJECT

This project aims to develop an international cooperation framework that promotes international team-teaching aligned with the European Education Area 2025 and labour market needs, including actions to support collaborative, international and experiential learning in engineering.

2.1 Partners

In the NextGEng project, there are three Higher Education Institutions (HEIs) and three companies from three different European countries (Finland, Romania and Spain) as full partners. *Table 1* shows the countries, names, acronyms and websites of the participating organizations, and also which work packages certain HEI partner leads.

Table 1. Full HEI and company partners of the NextGEng project.

Country	Name	Acronym	Website	Leader of
Romania	Technical University of Cluj-Napoca	TUCN	www.utcluj.ro/en	WP1 and WP3
Romania	Robert Bosch SRL	BOSCH	www.bosch.ro/en/	
Finland	JAMK University of Applied Sciences	JAMK	www.jamk.fi/en/	WP2 and WP6
Finland	Valmet Technologies Oyj	VALMET	www.valmet.com	
Spain	University of Jaen	UJA	https://www.ujaen.es/en	WP4 and WP5
Spain	Sensory Integration and Robotics	ISR	https://isr.es/company/	

The group of partners consisted of two large companies which are well-known around the world and one small and medium-sized enterprise (SME). VALMET is a global, leading supplier of process technologies, automation, and services for pulp, paper, and energy industries. BOSCH is a leading global supplier of technology and services. ISR is a start-up that was born as a spin-off from UJA. ISR has extensive experience in developing new technology solutions and products based on sensory integration and advanced automation for the industry, especially the agro-food sector. Two HEI partners are academic universities while one HEI partner is a university of applied sciences. TUCN is the main partner and coordinator of this project. TUCN has strong academic and research experience, which covers a wide range of engineering and science fields with outstanding results in promoting multidisciplinary and transdisciplinary activities. JAMK is a pioneer of hybrid and virtual education and one forerunner of pedagogical methods in Europe. UJA is one of the most innovative HEIs in Andalusia, Spain, in terms of scientific production and teaching quality, collaborating in initiatives devoted to innovative, virtual methodologies for engineering. The consortium comprises a comprehensive variety of different types of organizations and professionals. This provided very interesting and fruitful cooperation with different perspectives on each aspect of the project. Also, associated companies and institutions and several external partners around Europe follow the progress, utilize the results and perhaps also take part in some of the project activities.

2.2 Work packages

In the NextGEng project, there are six work packages which are Project management (WP1), Tailored training process (WP2), International team-teaching pilot program (WP3), Cases for experiential learning projects (WP4), Quality management (WP5) and Dissemination & exploitation (WP6), as shown in *Fig. 1*.

Three of work packages (WP2, WP3 and WP4) are implementation work packages which are explained in more detail in the following chapters.
The WP1 is led by TUCN and it takes care of overall project management and implementation. The WP1 provides guidelines, communicates with all partners, and periodically evaluates the project's financial situation, ensuring that the activities are implemented on time and according to the project plan. The project managers of full partners and work package leaders form the steering committee. The steering committee has a meeting every six months and during the whole project, only two of its meetings are face-to-face meetings. These two meetings are combined with the annual conference which is named the International Forum of Mechanical and Mechatronics Engineering (IFM^{2}E) and which is hosted by one of the HEI partners in turn.
The WP5 is led by UJA and it provides guidelines for quality assurance, monitors compliance of objectives' evaluation level and it also takes care of risk management.
The WP6 is led by JAMK and it takes care that all promised dissemination and exploitation activities are implemented in time and that the outcomes of different project activities are shared with full and associated partners of the project but also with a large audience.
Most of the meetings and activities of work packages are organized in hybrid and online ways reducing the need for traveling between the partner countries and at the same time reducing negative environmental impact. If travel is necessary for the organized international project activities and meetings, the participants will be informed and guided to choose green travel solutions. All reporting documents of the project are developed in electronic format and stored on the NextGEng MS Team cloud server reducing the need for printing documents.

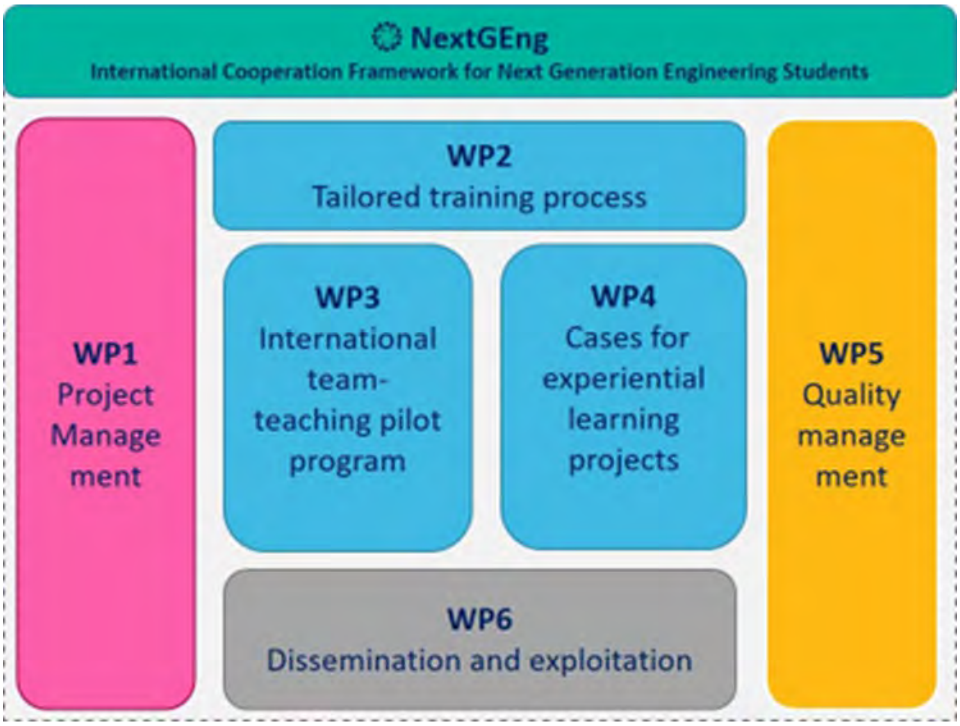

Fig. 1. Six work packages of the NextGEng project.

3 THREE IMPLEMENTATION WORK PACKAGES OF NEXTGENG

3.1 Tailored training process (WP2)

The main content of work package 2 is to design, develop and implement a pedagogical tailored training for the teachers of three HEIs. Experts in pedagogy and teachers with relevant expertise in new cooperative and international team-teaching methods sustain the skill improvement of teachers through workshops and guidance material. During the project, two rounds of tailored training stimulate teachers for innovative learning and teaching practices and the development of an international team-teaching pilot program (WP3). In the NextGEng project, the tailored training is organized by JAMK. JAMK as a forerunner in developing student-centered, competency-based education, digital learning, lifelong learning, and reforming work-related pedagogy and teacher training is the Leader HEI of WP2. The teachers involved in this WP are trained in team-teaching, problem-based learning, flipped learning, and student-centered learning methods. The teachers choose the most suitable methods and their combinations to be implemented in the activities of the following work packages (WP3 and WP4).

The first two-day tailored training seminar was organized at JAMK in January 2023. Many teachers from three HEIs and one expert from VALMET took face-to-face part in it while ISR and BOSCH experts were online. The first training day contained presentations and workshops in small groups. The topics of presentations were student-centeredness, international co-teaching, teaching methods, and digital tools. Also, a general presentation of the NextGEng project was part of the program. In workshops, teachers benchmarked each other’s teaching methods and tools. The second training day started with workshops in six international co-teaching teams. During these workshops, teachers started to plan and design six chosen courses in a student-centered way. They also together settled the next course updating steps after these training days. Next in the program, there were six presentations of the workshops' results. The first intensive and innovative tailored training seminar ended with a summary. The second tailored training seminar will be carried out in the spring of 2024 and will be organized in a hybrid way to reduce the traveling of partners.

3.2 International team-teaching pilot program (WP3)

The aim of work package 3 is to develop a pilot program that implements international team-teaching as a part of the educational process in all three HEIs for the engineering courses in their curricula. The leader HEI of WP3 is TUCN. Six engineering courses of every HEI partner's curriculum have been chosen to be upgraded by applying new teaching methods and updating existing content in close collaboration with company partners. The selected six joint courses contain both fundamental and advanced ones, and they are Strengths of Materials (C1), Industrial Automation (C2), Design Project (C3), Quality Assurance and Applied Methods (C4), Computer-Aided Design (C5), Manufacturing Technologies (C6). For each course, an international co-teaching team was formed that includes teachers from all three HEIs and company experts working together to develop new teaching materials and teaching methods. The first face-to-face meetings of co-teaching teams were at the first tailored training seminar at JAMK in January 2023. During the first project year (10/2022-9/2023), the upgrading process started with four courses (C1, C2, C3 and C4) and two other courses (C5 and C6) will be added to the process in the second project year (10/2023-9/2024). During the second project year, cooperative teaching implementation of four upgraded courses will be implemented as a part of the

teaching semesters in all three HEIs. During the third project year (10/2024-9/2025), cooperative teaching implementation of all six upgraded courses will be implemented as a part of the teaching semesters in all three HEIs.
The course upgrade process supports the development of new course materials in electronic form that is shared using online platforms with the enrolled students and presented to students during hybrid team-teaching sessions in which teachers and students participate face-to-face and online. After these two teaching rounds, the learning results will be evaluated and compared with the students that have followed the standard course program. During the third project year, the best practice guide for international team-teaching in engineering will be created and it will be published as a result of WP3 at the end of the project.

3.2 Cases for experiential learning projects (WP4)

The aim of work package 4 is to design, develop and implement two rounds of new student semester projects called Cases for experiential learning (CEL) projects where international student groups are involved in solving research or an industry-specific topic in direct collaborations with HEI teachers and company experts. The leader HEI of WP4 is UJA. The design of the CEL projects is shown in *Fig. 2*. In both CEL rounds, three projects will be simultaneously implemented, one in each partner HEI and country. In every project, six students from every HEI will take part in, so together 18 students. In every project, there will be formed three international teams of six students that will solve the same topic and compete against each other to create the best solutions for the proposed challenge.

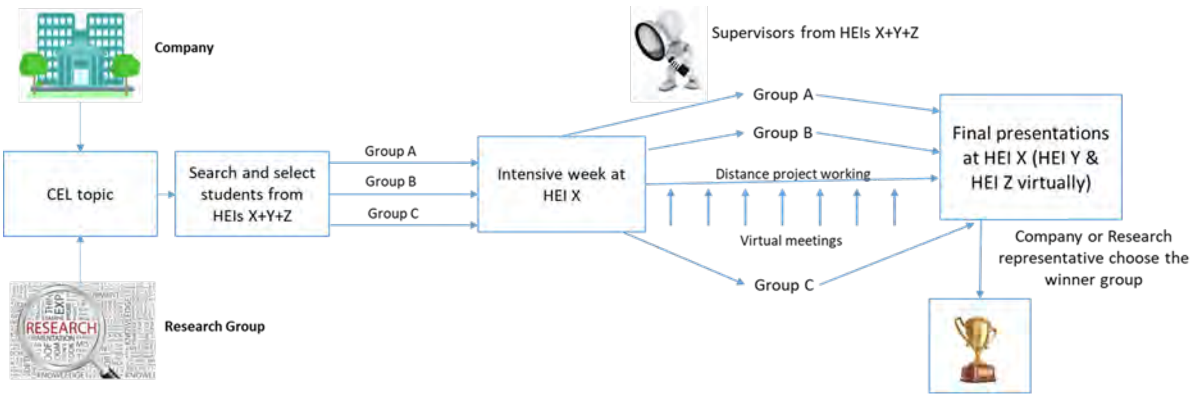

Figure 2. The design of CEL projects.

In the spring and summer of 2023, HEI teachers and company experts in three partner countries have together chosen the most suitable topics for three CEL projects. During autumn 2023, HEI and company partners will create info materials and write detailed plans for the first round of CEL projects. They also have info sessions for suitable student groups in their HEIs. After that, interested students will send their CVs to the teachers of their own HEI who will choose six students for all CEL projects. The first round of CEL projects will be implemented in the spring and summer of 2024 and the second round in the spring and summer of 2025.

At the beginning of every CEL project, there will be an intensive week in the HEI and the company where the topic will come from. All students, HEI teachers and company experts who will take part in a certain CEL project will participate in this intensive week. The student program during the intensive week will include tailored lectures, group work, group presentations, supervision meetings with teachers and company experts, and also some free time activities. After the intensive week, the student groups will continue solving the project topic remotely. The groups will regularly hold their own remote meetings where they will discuss the progress of the project and share outputs. Student groups will also have virtual meetings with teachers and company experts. At the end of every CEL project, there will be oral final presentations of student groups which will be organized in hybrid. Student groups also will write their final project reports. Teachers and company experts will evaluate the work of the student groups, choose the winning group and give grades to them.

4 SUMMARY AND ACKNOWLEDGMENTS

The three-year NextGEng project started at the beginning of October 2022. During the first project year, HEI and company partners have done all scheduled activities with a good attitude and on time. Cooperation between HEIs and companies has been innovative and fruitful. All participating organizations can learn new and useful things from each other and from this project.

The Tailored training process (WP2) is the first implementation work package whose activities will end and be ready in spring 2024. The most suitable methods and their combinations learned in WP2 are tested and implemented in two rounds of the International team-teaching pilot program (WP3) and in two rounds of the Cases for experiential learning projects (WP4) during the two last project years. During the academic year 2023-2024, cooperative teaching implementation of four upgraded courses and the first round of experimental learning projects are implemented as a part of the teaching semesters in all three HEIs.

The NextGEng project implements green practices at individual, institutional, and project levels. The aim is to reduce the environmental negative impact by reducing and optimizing the necessary travel activities, using digital tools for document management, raising awareness, and developing new green competencies for the target groups in the project. If travel is necessary for the organized international project activities and meetings, the participants will be informed and guided to choose green travel solutions that reduce as much as possible the carbon footprint of this mobility.

This paper has been developed within the framework of the “International Cooperation Framework for Next Generation Engineering Students” (NextGEng) project, co-funded by the European Union, with reference 2022-1-RO01-KA220-HED-000088365.

ABSTRACT

Teaching engineering students to navigate complex innovation ecosystems and deal with wicked problems is vital for contributing to sustainable development. Research shows that case-based learning with real-life challenges boosts motivation and learning outcomes. This paper presents a course that is in the core of an ecosystem where engineering students engage with hospitals, and work on the hospitals' documented innovation needs. By design, the course setup has a double purpose: in a learning context, the course strengthens intrapreneurship education, with students acting in an empowered role like professional consultants. In an organizational context, the course enhances knowledge sharing, filling in the gap of innovation competences and resources needed to create value and stimulate intrapreneurial initiatives. The ecosystem has evolved as result of an iterated development of the course including the tools and frameworks that empower the students to act as autonomous innovation consultants in constant interaction with the process of mobilizing the case partners. Thus, this paper presents a study based on current experiences and learnings, focusing on the relationship between the facilitation of student empowerment in live case-based learning and the impact on both 1) engineering students' motivation and learning outcomes; 2) value creation for the participating ecosystem. The paper builds on qualitative data from two sources: yearly follow-up interviews with case partners since 2018, and student reflection reports from 2022.

1. INTRODUCTION

After hosting a group of engineering students from an innovation course in the department, a senior consultant physician in a palliative care unit at a Danish hospital said that:

"[The students] have been super observant. It is wonderful to have eyes from the outside on such a messy shop as ours. They see some of the same things that I see, but they can say it impartially. It has been extremely useful."

Students wrote in a reflection report after another project at the same course:

"The doctor confirmed the skills we had learnt and were now using on the ward. It left us with a great feeling. We already felt we had made a difference by proposing concrete places to look to solve some significant problems. It was a much better feeling than getting an A grade."

These initial quotes remind us that the education of engineering students has become more than just teaching the technicalities of the engineering profession. Engineers nowadays are often placed in interdisciplinary contexts, where they work with complex problems, or so-called 'wicked problems' (Buchanan 1992). Moreover, it is often the case that the complexity increases when involving multiple stakeholders in intricate organizational webs. To prepare engineering students to their future professional reality, higher education institutions create and modify courses to expose students to real-case scenarios, interdisciplinary group work, and collaboration with organizational partners.

One example of an engineering program that aims to empower students to work in highly complex organizational environments is the bachelor study program of Process & Innovation, at Technical University of Denmark. The Process & Innovation study program educates design engineers. The students become generalists, and as it is written in the introduction at the university's website: "As an innovation engineer, you can help translate new ideas into concrete and usable solutions" ("Bachelor of Engineering (BEng) in Process & Innovation" 2023). The students "learn to work professionally with innovation and the implementation of new concepts, products, and processes from an engineering perspective" (ibid).

Early in the Process & Innovation study program, students are exposed to wicked problems, but the 4th semester course, entitled 'Innovation in an Organizational Context' (IOC), is their debut with live case-based learning in a professional context. Specifically, students in the IOC course work with hospital wards for 20 weeks.

The IOC course objectives aim:

"To enable the students to clarify, problematize and constructive relate to the relationship between organizational culture, knowledge dynamics, organizational changes and value creation, and the underlying socio-technological innovation ecosystem, and on that basis in praxis facilitate innovation in an innovation ecosystem" ("Innovation in an Organizational Context. Course Description" 2023).

In this practice paper, we frame the IOC as a case on how to facilitate student being part of an innovation complex organizational ecosystem. As outset, we consider that there are two main actors interplaying: the students and the professionals at the partner organization. Students act with an empowered role as professional consultants in the organizational ecosystem, whereas professionals act as contact points, i.e., sources of knowledge for students to explore the system and receivers of the finalized student project and derived value creation. These two actors have shared but also distinct expectations to be aligned.

Based on that, we investigate and discuss the following:

How does the expected value creation that meet the students in the organizational context in the ecosystem influence their motivation, learning outcome and self-efficacy?

We outline the course structure, the applied learning elements, and the process of mobilizing the ecosystem with support of empirical data.

2. METHODOLOGY

The paper builds on qualitative data from two sources:

- Follow-up interviews with case partners (hospital wards).
- Submitted student reflection reports.

Since 2018, 24 hospital wards have participated as case partners. In the same period 35 semi-structured follow-up interviews have been conducted. Typically, the respondents were the head of department and/ or the case contact person and, eventually, other staff members. The interviews have, with minor modification, followed an interview-guide, where questions were asked in four categories:

- The cooperation between students and the ward in general.
- The delivered outcome in the specific case.
- The perceived value creation.
- The effect of the students' presence in the department's work life.

The interviews have been recorded and transcribed. In the reflection reports, students ought to reflect on key events, on collaboration with the department, and on the group process applying Gibb's reflective cycle (Graham Gibbs 1988).

Both categories of data have been coded following a code list, including the terms 'value creation', 'trust', 'relations', 'process', 'expectations', 'optimism', 'motivation', 'feedback', 'engagement', 'ownership', 'efficacy' and more. In total, the analysis builds on 10 reflection reports and 35 follow up interviews from the period 2018 to 2022. Additionally, the paper also refers to course description and internal materials.

3. THEORETICAL BACKGROUND

3.1 Self-efficacy in live case-based learning

Case-based learning is an instructional approach broadly implemented in university education of nursing, medicine, law and business education, but that is still at its infancy in engineering education (Maslen and Hayes 2020). Case-based learning exposes students to cases, i.e., specific situations, scenarios, or problems that resemble real-world challenges they will encounter in their professional practice (Tripathy 2008). On way of implementing case-based learning is through live cases, where students are placed within an organizational context interacting with other key actors (Blomkvist and Uppvall 2012).

The practice of live case-based learning encompasses the idea of students perceiving themselves as being responsible for an outcome, while still having the support of their group mates and the facilitation of the supervisor. Tinto (2017) positions 'self-efficacy' as one of the key elements in the model of students' motivation and persistence in their education, together with 'sense of belonging' and 'perception of curriculum'. *"Self-efficacy is learned, not inherited"* (Tinto 2017), meaning students build their sense of self-efficacy from the experience with others and the situations in which they interact.

In this paper, we depart from the assumption that live case-based learning can potentially increase or decrease students' sense of self-efficacy, as they move along to work on their cases. Whilst a real case seems very challenging, students might increase self-efficacy if they find ways to navigate complexity, so that even difficulties on the way do not stop them to persist. We understand self-efficacy as a core element needed to be strengthened through practice of engineering education.

3.2 Value Creation in live case-based learning

In the last 20 years, universities have grown more entrepreneurial and have undertaken different forms of innovation collaboration with companies, comprising, for instance, students' live case-based learning (Perkmann and Walsh 2007). Live case-based learning has developed particularly important to partners who are new to innovation processes or that do not have enough dynamic capabilities to cope with innovation, such small enterprises, non-governmental organizations, and institutions like hospitals (de Silva and Wright 2019). Societal actors engaging with students can benefit from a multitude of advantages, such as access to skilled workforce, corporate societal responsibility efforts, ecosystem orchestration etc., while having a first evaluation of the efforts and outcomes of interacting with universities (Rafaela Hillerbrand and Werker 2019). Then, live case-based learning courses work as a platform that connect various actors to students and create reciprocal and shared value (Osorno-Hinojosa, Koria, and Ramírez-Vázquez 2022).

Nevertheless, as each collaboration is different and it involves actors with peculiar necessities, universities often struggle to balance out value creation for both the students and the interested stakeholder(s), but also value capture for itself (McAdam, Miller, and McAdam 2018).The difficulty comes from the nature of such shared value creation because value creation is both individually perceived and experienced (Lusch and Vargo 2006), and it is influenced by the different ecosystem in which each actor is contextually embedded (Jennifer D Chandler and Lusch 2015).

The case presented in this paper involves hospital wards, who revolve around their complex own ecosystem, multiple customers, and value creation strategy ("Budgetaftale 'Tid Til Patienten'" 2020), and students with separate logics. Therefore, while value creation is the objective of students' collaborations as a strategic capability that might drive actors' engagement and further the university ecosystem development (Orazbayeva et al. 2019), it also evolves along the interaction's deployment, as it is defined, discovered and evaluated, in intertwined feedback loops (Polese, Ciasullo, and Montera 2021).

4. THE IOC ECOSYSTEM

4.1 Course origins and design

The IOC course originates in the merge of two other courses: 'Innovation and Knowledge Management' (IKM), a 5-credit course lecturing an organizational curriculum, and 'Project 4' (P4), a 10-credit project course. Over the years, the two courses (IVL and P4) have gradually been integrated and continuously developed, as well as a network of partnerships was established, until they became integrated as IOC. The IOC course ran for the first time in Spring 2023 as a 15 credit, 20-week project-based course, where groups of students work with hospital wards as cases, one case per group.

The IOC course design uses 'active learning' and 'flipped classroom' as its key teaching methods. Students work in groups and need to apply the syllabus in practice ('active learning'). Each group is responsible for managing the workload from the course, which includes three mandatory deliverables, and one final implementation plan together with an 'innovation log' that documents needs and opportunities discovered through the process to the hospital department they are working with. To support their work, students are exposed to organizational theory, with literature available and have peer feedback sessions ('flipped classroom'). Moreover, there are several informal knowledge-sharing sessions in the class.

4.2 Hospital wards as cases

The first healthcare case was introduced in 2016, before IOC was created. The hospitals soon proved to be the ideal arena for learning innovation, as it says in one of the course guides:

"A hospital ward is a complex organization where changes constantly are taking place in a bubbling cauldron of citizens with needs and feelings, their relatives, professionals, and specialists from many fields who work together and are interdependent. It is a hierarchical organization influenced by political interests, financial requirements, and intense technological development" (Keiding 2023).

In 2018, it was decided to focus entirely on healthcare cases. Gradually, as a network of case partners has evolved, the course established itself as an actor in the innovation ecology in the hospitals.

4.3 The story about the course

The systematic documentation of the departments' experiences by follow-up interviews has played an important role in establishing the course as an actor in the ecosystem. A narrative has formed around the course, built from statements extracted from the interviews. Currently, value creation has become the selling point of the course for the hospital wards. This extract of the invitation letter to new wards exemplifies the emphasis on value creation:

“You have a busy life and there are probably several things you would do if you had the time. Why not let a team of engineering students do the work? You don't need to spend time formulating a case because that's the students' job. They must […] create the most value for employees and patients” (Keiding 2023).

5. EXPLORATION AND DISCUSSION

In this section, we explore the empirical data and discuss the topics introduced earlier. We use extracts from the data (i.e., quotes from student reports and follow-up interviews) to exemplify and illustrate key aspects identified.

5.1 Response from the real world

The learning outcomes from the students are closely linked to the response from the hospital partners, as exemplified in one student report from Spring 2022:

"Just as the department benefits from our new eyes on their work, we must also value their view at our work and recognize that it is not us and our high expectations to our own work that determine whether we make a difference for others, but it is actually them for whom we create value” (Group 8, 2022).

Here, the group let go of a self-centred approach to learning, shifting to a real-life focused approach, acknowledging that the project should be guided by the value creation perceived by the partner.

The value of having *“new eyes on their work”* is often apprised in the follow-up interviews, which demonstrates the individually perceived and experienced perspective on value in the case-collaboration (Lusch and Vargo 2006):

"We become blind to our own practice, so having our eyes opened by someone who comes from the outside and is not immersed in all sorts of things is insanely good” (Group 8, 2022).

The significance of the foreign glance seemed to be mutual since *“their view at our work”* is claimed by the students to be a central motivational factor, obviously more important than ”our high expectations to our own work”, a figure of speech that presumably refers to normative project assessment. What determines the quality of the project from the perspective of the students is *“to make a difference”* and to *“create value for [the hospital partner]”*:

“We must therefore become better at taking in the praise but also seek their validation, as it helped to create peace and confidence in our work. Specifically, we want to strengthen the contact with our stakeholders in the further work, to gain a deeper insight into their perception of our work” (Group 8, 2022).

It is a learning outcome to actively aim for a close interaction with the real world.

5.2 Accomplishing a value creating role in the ecosystem

Some student groups experienced to be seen as a resource in the hospital wards. A group took part in an ongoing project about home monitoring of heart patients:

"Through this process, we have gone from being observers to being key players in helping the department to further develop the use of Apple Watches. It has been enormously rewarding and motivating that [the hospital contact person] appreciates our labour and believes in our work. It has energized us and pushed us to be careful and thorough in our work" (Group 9, 2022).

The group accomplished a valuable role in the ecosystem. Their conclusion indicates a strengthened self-esteem:

"Our delivery from this course will be one of the cornerstones in the future maturation and implementation of the system" (Group 9, 2022).

5.3 Self-efficacy and the mobilization of the ecosystem

It is an important learning for students that successful value creation is not only determined by individual skills and a good solution, but by the ability to adapt to the ecosystem. Some actors demand hard work to mobilize.

In the following example, doctors and a senior consultant physician were the key actors, but the group had only been able to access the physicians through the ward nurse. The project took a major step forward when the senior consultant physician finally became interested in the project. All began at a meeting with the ward nurse:

"The meeting boosted morale within the group and increased motivation for future work. Prior to the meeting, it had been unclear whether the proposed solution had real value for the ward and we ourselves had begun to doubt its relevance. The ward nurse had a drive and enthusiasm that was contagious. She encouraged us to just go out and try the solution and gave full support to the project" (Group 11, 2022).

The ward nurse had no doubt that the group could win the staff for the proposed solution. Energized by positive expectations, they approached the physician:

"We were very motivated to continue the work and test the prototype because we felt that we had mobilized the key person [the ward nurse] for the implementation of the solution […] However, we ran into a problem when the situation did not allow us to just walk into a doctor's consulting room and demanded that they tested the prototype without the ward nurse present […]" (ibid).

The group conducted a workshop to create a *"direct link"* to the doctors. During the workshop, it became clear, that the doctors did not share the positive expectations of the ward nurse. A turning point occurred while an interaction played out:

"[…] when asked about whether the information about the waiting time can be registered and viewed in the Health Platform (SP), the consultant physician and another doctor shared knowledge. The consultant physician realized that the other doctor has been using the Health Platform differently, with the effect that the current delay in relation to the schedule was visible to the entire staff" (ibid).

The debated feature was of value to the doctors since the registration happens automatically and reduces interruptions.

“The consultant physician ended up asking the facilitator [one of the students] whether the proposed solution would be a technical possibility” (ibid).

The workshop did not establish the wished *“direct link”*, but it made the students of use to the doctors. The situation led to an important learning:

“The idea of having to facilitate a person who has the daily leadership role was very challenging and made it difficult to stick to the framework and purpose of the workshop. […] However, the workshop resulted in great joy as the doctors started to share work process experiences internally. This is where the effect of the workshop really came into play, and it was a feeling of success to have "overcome" the participants who probably represent the most difficult to mobilize” (ibid).

This is a case of confirmation of the professional capability of the group. The doctors did not directly praise their proposal, but a change in perception occurred and confirmed the process, and thereby the professional capability of the group to manage that. *“This is where self-efficacy is learned”* with the words of Tinto (2017).

6. CONCLUDING REMARKS

6.1 The ecosystem evolves

In general, there is a positive dynamic in the ecosystem, pumped by a high degree of expectations from both case partners (i.e., hospital staff) and students. Hospital staff warmly welcomes the new students with expectations that they will create value and produce good results as their past cohorts. Students, on the other hand, are motivated to make the efforts to these meet expectations. In most cases, they succeed and add to their professional ethos and self-efficacy.

Later in the study program, some students continue with their projects or other projects in the healthcare sector and become role models to the new students. At the hospitals, among the healthcare departments, the word about the IOC course and the results are spread when managers bring the results to various forums and when staff move to new positions elsewhere in the sector.

6.2 Final notes

This practice paper takes the ecosystem perspective on value creation and uses the example from the IOC course to explore the interconnectedness between students’ motivation, self-efficacy, and learning outcomes, and the value creation for the case partners.

With this paper, we do not present a simple answer to the question raised, but a – still hypothetical – model seems to emerge. The learning dynamic plays out in a multi-connected feedback loop formed around 4 key concepts:

- Value creation in one year leads to positive expectations from the hospital wards towards the students in the next year.
- Positive expectations are expressed in a welcoming attitude from hospital staff and leads to strong student motivation.
- The students benefit from the strong motivation in the form of enhanced self-efficacy and learning outcomes.
- Enhanced learning outcome goes together with improved value creation for the wards.

The model is expanding as the ecosystem is mobilized, both by the students as a mean for them to learn and in the process of recruiting more department as cases. In the end, to the students, the dynamic seems to be able to provide a lot more *“than getting an A grade”* in terms of self-efficacy and motivation.

ABSTRACT

For many engineering students a lack of study motivation plays a significant role in their drop-out process (Heublein 2014). Therefore, students' motivation to study should be encouraged as early as possible. A proven strategy for increasing the study motivation is the integration of project-based learning (PjBL) in the course of studies (Kokotsaki et al. 2016).

This paper introduces a PjBL-workshop concept which was developed for first-year energy engineering students at a university of applied sciences in Germany. During

melanie.kitzig@hs-ruhrwest.de

this one-semester workshop, the students are working weekly as student trainees in a fictitious engineering office. Guided by the teacher as the project lead, the students are developing a concept for integrating various renewable and sustainable energy systems in a single-family home. Each week they take on subtasks of a different work package supporting other employees of the engineering office. During their time as student trainees they have to face authentic engineering challenges like constructing a photovoltaic plant or dimensioning a battery system. Progress and results are documented in a project journal.

First insights of initial implementations of the concept led to a closer focus on the aspect of the perceived authenticity of the PjBL-setting (engineering office) by the students. Therefore, besides the conceptual and contentual design of the workshop, this paper will also address the creation of the authentic setup of the engineering office.

Future research in this ongoing study will examine the influence of the perceived authenticity on various aspects such as the motivation to study.

1 INTRODUCTION

The demand for well-trained engineers has never been higher. However, institutions of higher education are still struggling with increasing dropout rates in engineering study programs. As a main reason for their dropout in the first semesters many students state a lack of motivation to study (Heublein 2014).

One strategy to counteract these dropout rates can be the integration of the student-centred (Kokotsaki et al. 2016) approach of project-based learning (PjBL). This method is widely used in engineering education (Chen et al. 2020), provably increases the students' motivation to study and provides many benefits and engineering skills for students, like enhanced critical thinking, independent learning (Frank et al. 2003) and improved problem-solving skills (Harmer and Stokes 2014).

In order to promote the study motivation as early as possible, PjBL should be used from the beginning of the study program. In this paper, a PjBL-based workshop for first-year energy engineers will be introduced. Therefore, the challenges of the PjBL implementation, the framework and the structure of the workshop-concept will be described. An overview of the content design of the workshop will be presented afterwards. In addition to the conceptual and content design, this paper will also focus on the design of the authentic setting. Finally, an outlook on the next steps in this ongoing study is provided.

2 PROJECT-BASED LEARNING

Defining PjBL is challenging due to different understandings of the term in different countries and disciplines (Harmer and Stokes 2014). Sometimes it is used similarly or interchangeably with problem-based learning (PBL) (Harmer and Stokes 2014). Differences and similarities between these two approaches will thus be discussed later in this paper.

PjBL can be considered as a particular type of inquiry-based learning (Kokotsaki et al. 2016), as many elements of PjBL are derived from this method (Frank et al. 2003). Inquiry-based learning itself is based on the constructivist teaching approach, according to which students learn concepts or construct meaning through their interaction with others and their world (Frank et al. 2003). Therefore, three constructivist principles are forming the fundament for PjBL (Kokotsaki et al. 2016): (1) learning is context-specific, (2) learners are involved actively in the learning-process and (3) learners achieve goals through social interaction and sharing of knowledge and understanding. From these principles, seven main characteristics of PjBL can be deduced.

2.1 Main characteristics

In accordance with principle 1, the context of learning for PjBL is provided through *authentic driving questions* within real-world problems (Kokotsaki et al. 2016), which form the fundamental element of the project. These complex and open-ended problems are often identified by the teacher and further developed by the students during their investigations (Harmer and Stokes 2014). Essential for the approach is, that the outcomes or solutions for the problems are not predetermined, so that the students have a flexibility in their problem-solving process (Harmer and Stokes 2014).

During their investigations the students are involved actively in the learning process (principle 2) (Kokotsaki et al. 2016). Active here means *learning by doing*. The students' role changes from the traditional, passive listener to an active maker (Harmer and Stokes 2014). Hands-on experience in practical projects strengthens the connection and identification with the faculty and gives an informed view of the target profession (Harmer and Stokes 2014).

To take more responsibility for their own learning, the projects are mainly student-driven (Kokotsaki et al. 2016). With a high degree of *autonomy*, the approach leaves space for developing own methods and procedures (Harmer and Stokes 2014).

Whereas student independence increases, the teacher moves more into the background and acts as a facilitator or a mentor during the project (Kokotsaki et al. 2016, Frank et al. 2003, Harmer and Stokes 2014). As often found in the literature the shift of the teachers' role can be described as from a 'sage-on-the-stage' to a *'guide-on-the-side'* (Harmer and Stokes 2014). The teachers' task is to create a contextualised learning environment, that allows students to construct their own knowledge (Frank et al. 2003), while balancing their need for support and autonomy (Harmer and Stokes 2014).

The third principle indicates the need for social interaction and collaboration in the learning process (Kokotsaki et al. 2016). PjBL is based on *team work* where students learn important skills like interacting, communicating and planning as a preparation for their future everyday engineering life (Harmer and Stokes 2014).

PjBL-projects often either cross or combine multiple disciplines (Harmer and Stokes 2014). *Interdisciplinarity* enables a differentiated view of the boundaries of one's own discipline and the points of connection with other disciplines.

One of the most distinguishing features of PjBL is the creation of an *end product*, which drives the whole process of planning and realisation of the project (Harmer and Stokes 2014). The types of outputs or artefacts vary from real products (Frank et al. 2003) to presentations and reports (Kokotsaki et al. 2016). The end products are usually shared with an authentic and appropriate audience, like fellow students or teaching staff (Harmer and Stokes 2014).

2.2 PjBL vs. PBL

The construction of an end product or concrete artefact is not only the most signifying element of the PjBL approach, it is at the same time the feature that distinguishes it the most from the related PBL approach (Kokotsaki et al. 2016).

Both approaches are based on similar principles with focus on problems with relevance to the real world. The two of them are working with collaboration of the students (Kokotsaki et al. 2016) and facilitating teachers. The main difference between them is, that PBL primarily concentrates on the process of learning (Kokotsaki et al. 2016) or producing a plan or a strategy (Harmer and Stokes 2014), while PjBL focusses on the creation of a real end product (Kokotsaki et al. 2016) or carrying out a plan (Harmer and Stokes 2014). The challenge is furthermore, that these two terms are sometimes used equally, distinguished or combined, depending on the discipline, the country or the regarded research group (Kokotsaki et al. 2016). In this paper, these two approaches are considered as similar but distinct.

2.3 Challenges

Implementing PjBL with all its elements is challenging. In the literature, a wide range of challenges is reported. Chen et al. (Chen et al. 2020) identified several challenges on individual, institutional and cultural level for students and teachers, the most on the individual level. For the teachers, a lack of training as facilitators and the choice of assessment is the main challenge. For the students, it is the lack of teamwork skills, self-learning skills and project management skills that causes problems (Chen et al. 2020). Harmer and Stokes (Harmer and Stokes 2014) and Kokotsaki et al. (Kokotsaki et al. 2016) each present a set of recommendations to master these challenges.

2.4 Authenticity in PjBL

Furthermore, Strobel et al. (Strobel et al. 2013) address a concern regarding the design of authentic learning environments, like in the PjBL approach. ‘What is considered authentic to the teacher is not necessarily authentic to the student’ (Strobel et al. 2013, p. 144). In addition to that, the term authenticity is ‘often used without reflection or clear definition’ (Strobel et al. 2013, p. 144).

According to Bialystok (Bialystok 2017), in order for something to be perceived as authentic by the students, it does not have to correspond to the actual reality, but to what students assume to be their personal reality. Therefore, it will be important and necessary to know the students' personal reality regarding the project scenario or the project environment in order to be able to provide them with an authentic experience during the project.

3 PROJECT-BASED WORKSHOP

The following chapter introduces a workshop designed according to the characteristics of PjBL presented in section 2.1. First, the framework conditions for the workshop are explained, afterwards the implementation of the PjBL elements is described in detail.

3.1 Framework conditions

The PjBL-workshop is part of a mandatory first-semester introductory course for freshmen of two energy engineering study programs at a university of applied sciences in Germany. The study programs share basic courses and specialise towards energy systems or energy information technology. The course consists of a lecture (3 hours per week) and the weekly practical PjBL-workshop (2 hours per week) and has 6 ECTS. The semester lasts 15 weeks, whereby 2 weeks are provided as self-study weeks and are thus omitted as lecture weeks. The grade for the course is composed of 70% of the assessment of the lecture and 30% of the workshop, what will be described in detail in the next section. The lecture will not be discussed further in this paper.

During the winter semester 2020/2021 the workshop was performed as a reduced online version due to the pandemic situation. The course started with 40 active participants and finished with 35. In the winter semester 2021/2022 the workshop could be carried out in presence in its intended version. At the beginning of the semester, the number of participants was 34 students, which dropped to 25 by the end of the semester. The reason for dropping out of the course was mainly due to dropping out of the entire degree programme or changing the degree programme. The attendants of both years were mainly first-year students, a small amount was from higher semesters.

3.2 Implementation of PjBL

The story for the authentic scenario in this PjBL-workshop begins with a young couple, who bought an old single-family home from the 1960s. They hire an engineering office to develop a concept for the integration of renewable and sustainable energy systems to their new house, as they want it to be fully renovated and modernised. Working as freshmen student trainees in the engineering office, the students are involved in this new project. By taking on subtasks of different work packages every week, they support other employees of the fictitious office.

The described authentic driving question of this project is identified by the teacher, who acts as the project lead here. The project is already pre-structured into work packages. This intends to give the inexperienced first semester students in particular a framework or common thread for their project. However, in compliance with the PjBL characteristics the outcomes of the work packages are not predetermined and the students have space for their creativity and can experience different tools and methods to solve the driving problem. They are involved actively in the process of developing and designing the sustainable energy system concept, which represents the intended end product of the project.

Each workshop session starts with an opening by the project lead (teacher), where the tasks and sub driving questions for the current work package are presented. Working material is provided through the online learning platform Moodle. Tools and software needed for the next session are introduced in videos, so that the students can prepare themselves in advance. After the weekly introduction, the students work mainly autonomously in teams of three. The teacher takes on the passive role of a facilitator and provides support if needed.

The project is divided into three phases. Table 1 gives an overview of these and their corresponding work packages, including the number of weeks dedicated to each work package. Further, the used methods for each work package are described.

In the preparation phase, the students get an introduction in skills they need for their work in the engineering office. They are already working in teams, but the composition of the teams is still flexible and vary each week in this phase. This serves the purpose that the students should first get to know each other better before forming fixed teams, since they are new to the university. The students learn how to organize themselves and communicate within their teams and how to communicate with the project lead. They write a guideline about the characteristics of scientific literature, how to find and identify it. Furthermore, they deal with the appropriate documentation of results and work progress.

From the fourth week onwards, the students form fixed teams of two to three by their own choice, which remain unchanged until the project ends. The execution phase starts, in which the actual project is processed. Each team member documents their teams project progress and weekly results in a personal project journal. In addition to that the students also write down personal reflections of the project process in their project journal. At the end of the week, the journal entries are uploaded to the Moodle platform and reviewed by the project lead. Review criteria are completeness, technical correctness in the documentation and accuracy of the notes as well as the focus on the project aims. The personal reflection part is not subject to a separate assessment, but should be structured, self-reflective and critical.

During the project execution phase, the students work on four different work packages of interdisciplinary topics. Each team will work on the same work packages. The teams' project outcomes, nevertheless, will differ since each team will make its own decisions and use its own approaches.

Table 1. Content and methodological structure of the workshop

Project phase	Work package	Methods and social forms	Number of weeks
Preparation	Communication for teamwork	Group discussion, plenum discussion	1
	Research on scientific literature	Literature research, report writing	1
	Documentation of work progress	Investigation of negative examples	1
Execution	Photovoltaic plant	Inquiry-based learning with simulations, software usage	3
	Battery system	Literature research, choices based on solid justifications	1
	Solar thermal system	Visit of a real plant	1
	Pellet heating system	3D-designing, 3D-printing, peer review	3
Completion	Presentation of the energy concept	Oral team presentation	2

The project begins with the design of a photovoltaic plant for the house. First, the students investigate the solar orbits during different seasons by simulations to understand how to find out the perfect position for the plant on the roof. In the following two weeks the students use the designing software PV*SOL to plan the actual photovoltaic plant. The next work package deals with the dimensioning of the battery system. Here the students examine different types of battery technologies and should give a recommendation for the clients' house, based on literature research. After finishing the electrical supply for the house, the students plan the thermal supply. A solar thermal system is to be installed to heat the domestic hot water. The students visit the solar thermal system of the university and learn about the elements of the system and their functionality. Afterwards, they have to design a system diagram for the clients' house, in which they have to apply the newly gained knowledge from the inspection of the actual plant. In the following three weeks, the students plan a storage room for pellets to be used in a pellet heating system. In this work package, the students build a ramp structure to slide the pellets to the exit of the pellet room towards the heating. The work package includes designing the ramp in Autodesk's 3D software environment Tinkercad, creating it in a 3D printer, and testing and evaluating one's own ramp and that of another team.

In the last phase, the project is concluded by a team presentation in which the students present their elaborated results and thus their developed sustainable energy concept for the house as their end product of the project. The audience consists of the other teams, the project lead and other members of the engineering office, represented by teaching staff of the university. The engineering office members and the project lead evaluate the presentations of each team and decide which concept is finally realized and presented to the clients. For the assessment of the whole workshop, team and individual evaluations are combined. The grade is composed of 50% each of the evaluation of the team presentation grade and the weekly project journal grade.

In this implementation of PjBL, all the main characteristics presented in section 2.1 have been successfully integrated. Nevertheless, the point of interdisciplinarity might not necessarily be implemented as it was originally intended. The workshop is composed of work packages that all come from the field of energy engineering. However, energy engineering itself is interdisciplinary and consists of many different disciplines, such as electrical and thermal energy generation, distribution and storage, different sorts of renewable energies and energy efficiency. Therefore, the workshop demonstrates the interdisciplinarity of energy engineering so that first-year students get an orientation in their chosen field and a first impression of the interdisciplinary challenges they have to face during their studies and their further professional life as energy engineers.

4 EVALUATION AND RESULTS

4.1 First survey and interviews

After the first realisation of the workshop in winter semester 2020/2021, the students took part in an online evaluation consisting of a questionnaire. The intention of the evaluation was on finding out how the students assess the implementation of the PjBL elements, the engineering office scenario itself and the learning materials from their point of view and where they see potential for improvement. Additionally, five students had been chosen for a guided interview to obtain more detailed insights of the evaluation of the PjBL concept. The results showed a high acceptance of the concept and the idea of the engineering office setting. The level of difficulty of the work packages was assessed as mostly appropriate. The students could well imagine that they would have to complete such tasks as real student trainees, since they never had to bear the complete responsibility for the work package alone, but rather work alongside the permanent employees from the engineering office. The above-mentioned challenges for students could be also mastered well mostly. Especially the lack of teamwork and project management skills was well supported during the preparation and execution phase. The students were motivated and enjoyed their creative space during the project.

According to section 2.4 one main challenge identified was the difficulty in implementing the authentic learning environment. This was also apparent in the interviews. The engineering office setting was not always present and authentic for the students. Sometimes they forgot that they had to take on the role of student trainees. The change from the participant in a university course to an employee in an engineering office was occasionally difficult for them. Moreover, it was not always easy to see the teacher in the role of the project leader rather than the university member and rater.

4.2 Exploratory survey on student’s reality of an engineering office

To enhance the understanding of the students’ imagination and mental picture of an engineering office, a written survey with open questions within a questionnaire was conducted at the beginning of winter semester 2021/2022. Uninfluenced by the following confrontation with the designed engineering office setting in the workshop, the students should describe how they imagine an engineering office, what they associate with that term and what experiences they might already have gained. The questionnaire contained questions like:

‘*Name the first 3 words you associate with the term engineering office.*’

‘*How do you recognise an engineering office? What do you think is typical for an engineering office?*’

‘*Have you worked in a real engineering office yourself or do you know someone who works or has worked in an engineering office?*’

The majority of the students have never worked in an engineering office themselves or know someone who does. Mostly, they described typical elements of offices for architects or civil engineers, like open space offices and technical drawings pinned onto the walls. These elements are in contrast to typical classrooms of universities.

The results of the survey will therefore be used to create a more suitable learning environment for the PjBL-workshop, which will be designed as the students imagine an engineering office and will look less like a classroom. The intention is to overcome the classic teaching patterns and to literally give the new roles of students and teachers a new room to develop.

5 CONCLUSION AND OUTLOOK

This paper introduced a PjBL-workshop for freshmen energy engineering students with details of its content and methodological structure. As already mentioned by Strobel et al. (Strobel et al. 2013), the main challenge for the implementation also was identified as the creation of the authentic problem-solving environment, since what is authentic for students is not necessarily what teachers consider it to be. Although the majority of the participating students have not yet had any direct or indirect experience with an engineering office, they already have an image of it. Influences of this on their perceived authenticity of the PjBL-setting will be investigated in the further study. This ongoing study will also examine the effect of the perceived authenticity of the PjBL-setting on factors like the study motivation, the intrinsic motivation for the project or the individual and situational interest for the project topic.

Strobel et al. (Strobel et al. 2013) additionally pointed out, that there is a need for robust models and operational definitions of authenticity, especially in engineering education. Investigations regarding the effects of authenticity on learning outcomes are needed.

Therefore, in further steps of this study, a model of perceived authenticity, including an operationalisation, will be developed on the basis of the presented PjBL-workshop concept.

ABSTRACT

University students are asked to become all-round human beings, knowing how to be engaged in Engineering in the future, as well as wholly socialised and going through personal development steps. However, how and where are the students supposed to acquire these skills? Do we already have them in the Higher Education programmes and curricula? This article explores low threshold steps that can be taken to tweak the curriculum and implicit professionalisation of staff towards incorporating transversal skills and reflective activities that allow students to develop to their full potential.. One is a roadmap

Workshop identifying guiding principles and touchpoint activities for curricular change. The other is a survey on how transversal skills are currently thought to have been embedded in the curriculum

1 INTRODUCTION

According to Biesta (2009), the current pedagogical assignment for education is the tripartite development of students on qualification, socialisation and subjectification. Qualification ensures our students in Higher Engineering Education become competent in one or multiple disciplinary engineering fields. Socialisation relates to students becoming aware of the values and norms embedded in academia and the professional environment they will enter after graduation. Subjectification is an ambition to develop the qualification, socialisation and who they become. This pedagogical ambition requires repurposing and (re)shaping the university's curricula.

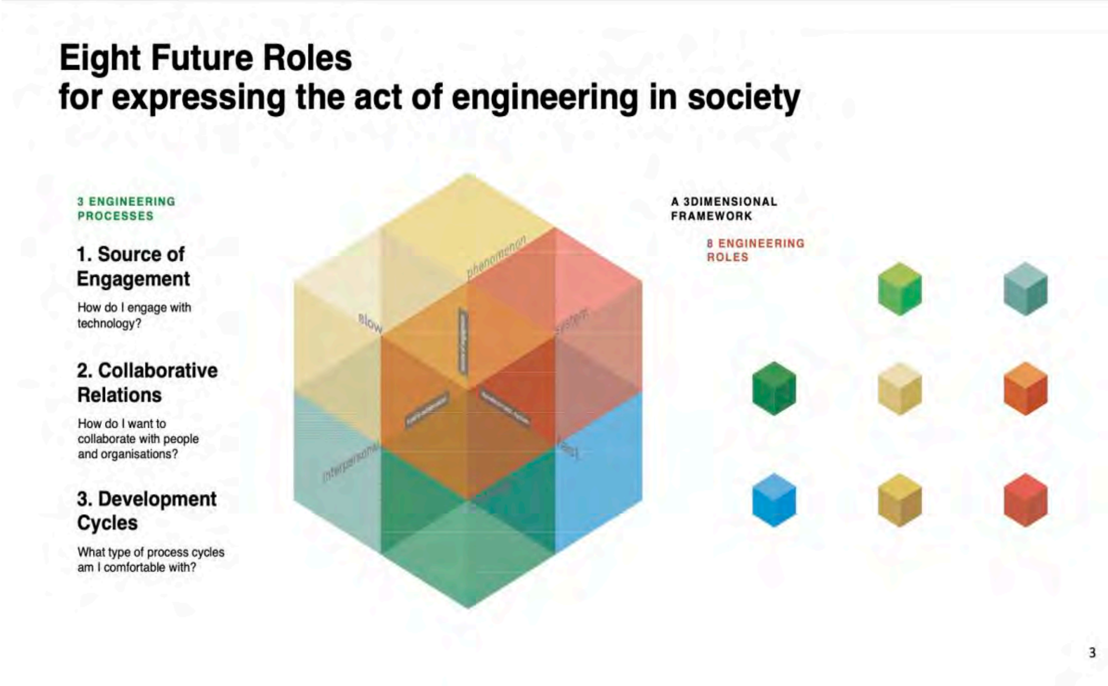

Fig 1. Engineering Roles

In the Bio-Medical Engineering (BME) programme, we have embedded a design-based vision of the future engineer. The Vision in product design methodology has been used to create engineering roles with the involvement and interviewing on expert interviews in the field, literature reviews and validation workshops. The Vision suggests three dimensions our students will encounter in their future engagement with technology. These dimension of engagement with technology, collaboration models and fast and slow production cycles helps students to become all-round engineers (Klaassen et al., 2020). The emergent engineering roles from the dimensional framework are a guiding tool for going through a reflective cycle of development leading to subjectification, socialisation, and qualification. Transversal skills are used to ground the socialisation process of future engineers in the BME context, and qualification is supported by the acquisition of BME knowledge and skills and subjectification through role-focused reflections. Table 1 includes an overview and its intended relationships and as expressed in the BME curriculum.

Table 1. Framework for curriculum adaptation

Engineers should be able to adapt to a changing environment,	Phenomenal/societal challenges addressed.
Engineering Role identification	
Take agency for their own learning/learning path, in which *agency* is defined as the ability to act based on your reasoning and understanding yourself in context.	Reflection and positioning concerning individual engineering roles in relation to the world.
Socialisation:	**Collaborating in technology**
Use engineering topics to interact with the world,	Preferred ways of working on basis of interpersonal trust or via rules and regulations of a system
Engineering Role in action	
Take responsibility for shaping future practices,	Reflection on preferred ways of working as an engineer
Qualification:	**Dimension**
Develop a continuous lifelong learning loop.	Acquisition of skills/ knowledge/ attitudes for slow and fast development cycles of production
Engineering role application	
Critical assessment of professional standards through engineering knowledge/skills practices	Reflection on theories, tools and methods needed.

2 METHODS

In this curriculum development process, we have chosen to determine a roadmap for implementing an environment beholding these pedagogic and dimensional elements from Biesta and the Vision of the future university (Biesta, Klaassen et al.2020). The idea was to create a maximum impact with minimal effort from the teachers involved N= 6. The 1st part of the curriculum development consisted of a start/– stop/continue approach to activities within the curriculum. To prepare teachers, we have undertaken activities that supported the creation of an understanding of the courses concerning the

Vision, mapping where we wanted to operate/tweak courses on a meta-level and designing supporting materials needed for teachers to implement the created framework. In general, activities to generate implementation or guiding principles included workshops with teachers, interviews and surveys with students, teacher surveys on sub-elements etc. This paper reports on one of these workshops and a teacher survey.

In this particular teacher workshop, a brainstorming activity was conducted on a student learning journey map with touchpoints within the Master curriculum that served as a timeline for embedding educational interventions or desired activities in education. This brainstorm has successively served as a basis for input into a roadmap, including six guiding design principles for curricular development, that included the three pillars of Biesta and the dimensional features of the future university. The intention was to support teachers in the programme in identifying; how these framework ideas could apply to their courses, what is already present in their courses and whom they can ask for help if they want to change their curricular design. These principles will allow them to easily insert and embed the new merged Vision on education, addressing both Biesta and the future vision model. In a follow-up workshop, they were asked to rephrase their learning objectives to align the vision framework with practical courses.

The teachers of all the courses N = 12 were also asked to fill in a questionnaire to find out which reflective, contextual skills and engineering skills were already used in the 18 courses offered within the master curriculum. Teachers could answer: (1) students are already trained on these skills, (2) not trained on these skills and (3) not trained on these skills, but I would like to add them to my course. The skills were provided with an explanatory definition.

2.1 Workshop Assignment and Methodology

According to the developed principles, the university is required to realise a safe context in which experimentation and failure are a part of the learning process. This idea of a safe context propagates programmatic assessment in which multiple performance measure moments are embedded, and 360-degree stakeholder input and stepping away from past failure are new focal points. These six Guiding principles steps described in the next section, should facilitate the reshaping of this curriculum endeavour and support students in going through iterative rounds of reflection related to subjectification, socialisation, and qualification elements. Reflection encompasses "whom students want to become with help of the engineering dimensions", "how students act in the outside world", "how students can understand and influence future practices and "how students can change the future

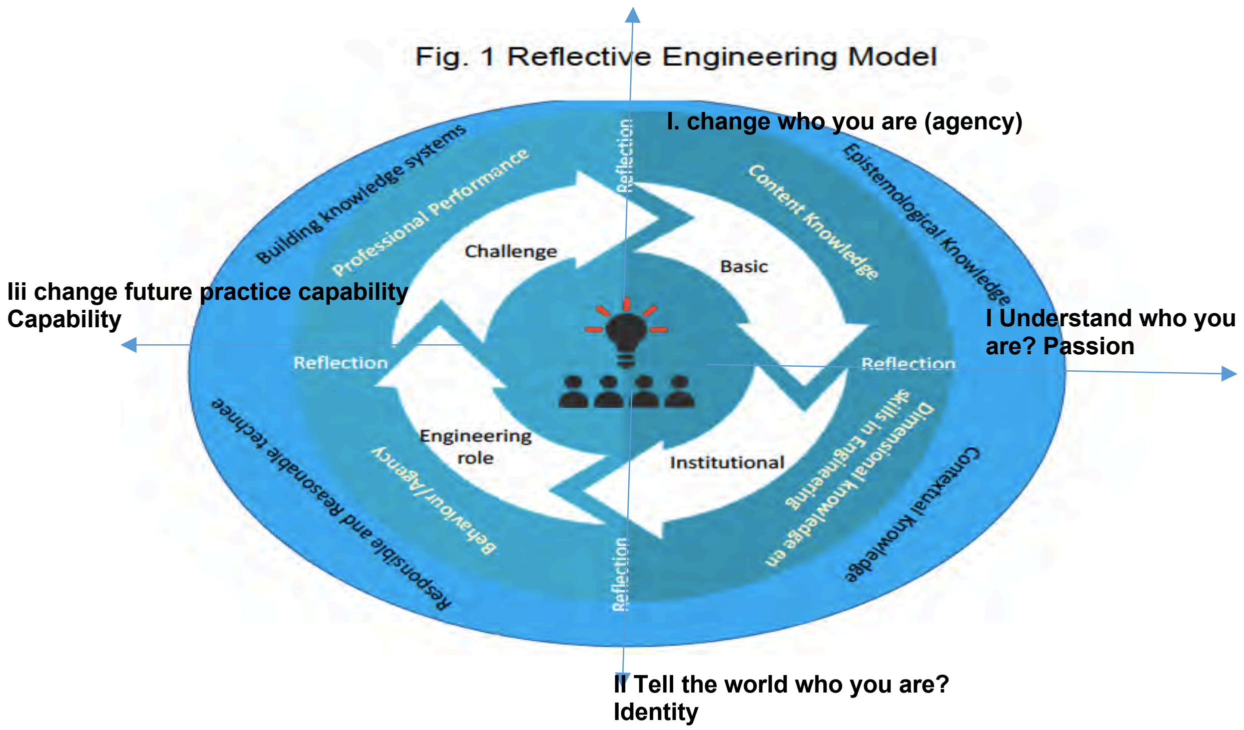

Fig. 1 Reflective Engineering Model

Skills and knowledge are part of the light blue and turquoise circle in Fig. 2. of the reflection cycle. Disciplinary & epistemological knowledge for medical, biological, and engineering knowledge and what is probable, possible and impossible is necessary for existing and changing practices. Engineering skills help students position themselves in practice and make technical decisions. Contextual skills include becoming aware of and responsible for the consequence of actions (ethics) that are taken or not taken concerning doing, saying and knowing in practice. Furthermore, finally, reflective skills include understanding one's position in context and practice and being capable of acting based on one own reasoning (Trede's, 2019). However, the key question here for the teachers is on how to embed this in their curriculum or programme. The Roadmap workshop was designed to answer this question.

3 THE ROADMAP WORKSHOP

In a workshop setting, these profiled ideas have been benchmarked with the lecturers, who mainly favoured adopting these suggestions while equally discussing further refinement and adaptation possibilities within the curriculum along a transition moment timeline. Transition moments are, for example, choosing a master track or a thesis topic. Suggestions mainly focused on providing role models embodying the engineering roles in the BME field and learning from interaction with these people.

Teachers were, however, equally expressing concerns about the need for more time to embed these elements and for the students to adapt these skills. E.g., the question is if they need to be assessed in the curriculum and when, in reflection documents, who will do the work. Who has the ownership of reflection documents etc? Moreover, whether these really add value to the curriculum.

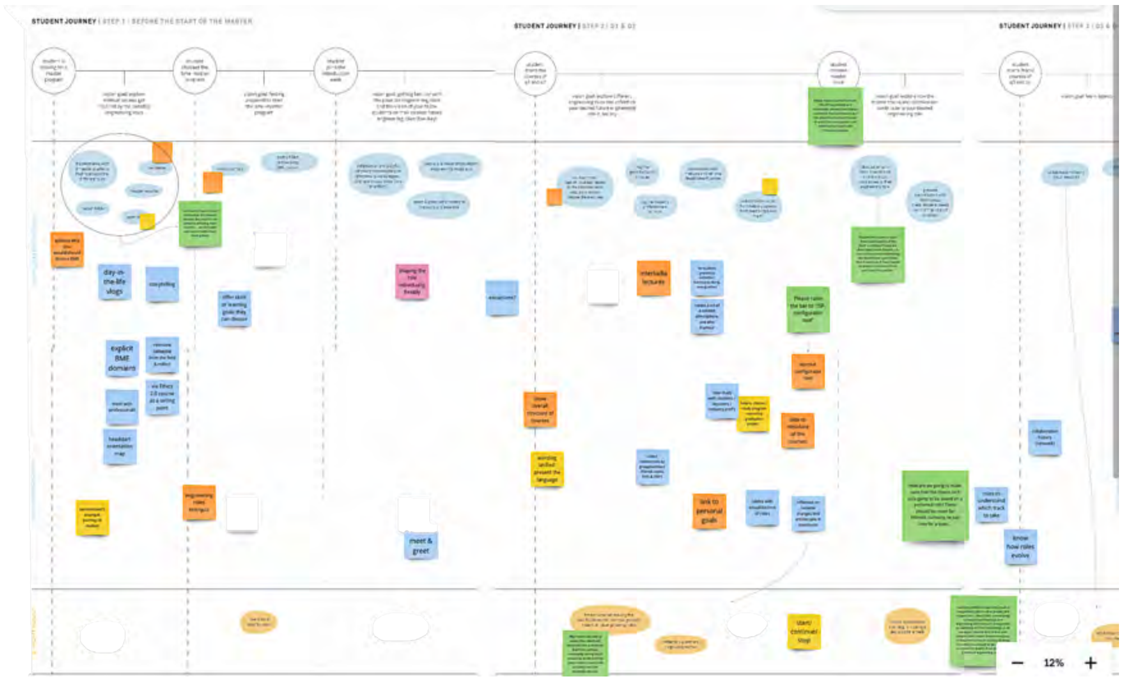

Fig. 3 ideas to embed in the curriculum (post its on roadmap)

Nevertheless, the workshop resulted in 6 guiding principles for curriculum design that would meet the engineering vision's original dimension and address the pedagogical assignment of Biesta. Before the Master, students should be given ownership of their learning experience, providing information about the possible engineering roles and reflective activities to motivate and challenge their attitudes. This reflection might be realised at the open day, introduction day or through other introductory media, such as conversations with people from the field, a video documentary of "a day of…".

Another option is the focus on diverse role models presented in the kick-off week, which students use to reflect upon the responsibilities and mission the future engineering students will likely encounter. In the first workshop, students presented their future engineering manifestos (read reflections) in groups. This manifesto helps students decide on their desired Master's track. During the Master, there were many more suggestions for embedding ownership, such as reshaping assignments into challenges involving external stakeholders, flexible choosing which challenges to work on in a team and using engineering roles to set up personal goals, translating (transversal) skills into the learning objectives, and contextualising the course to a greater extent

3.1 Guiding Principles

01 Translating own reasoning into personal goals (subjectification): Setting personal learning goals is supported by identifying a knowledge-skills-matrix and in which courses these can be acquired within the BME master. BME Knowledge and Skills are categorised at different levels; disciplinary, engineering skills, contextual and reflective skills. A reflection portfolio might support the evaluation of these personal goals.

02 Experimenting with forward reflection (subjectification) – reflection is introduced using future engineering roles we expect will be relevant in 10 years and can guide students and help them shape their futures. Analysing the knowledge, skills and development path of favourites in the field on a dimensional level helps to shape a personal future profile, using principle 01 to get there.

03 Taking an ethical stance and acting responsibly (socialisation) – is about being aware of what product and research results are distributed and adapted into the world. Reflections on how they interact with the world and their actions' impact are vital socialisation aspects for the students (Walcott et al., 2019). Case studies and explicit evaluation of challenges in team settings should guide the learning process.

04 Supporting pivotal transition moments – students discovering their way of being and supporting the transitions to help students get a more straightforward learning path is pivotal for subjectification. Students presenting and upgrading their manifesto regularly with supportive feedback from peers and professionals help navigate the pivotal moments.

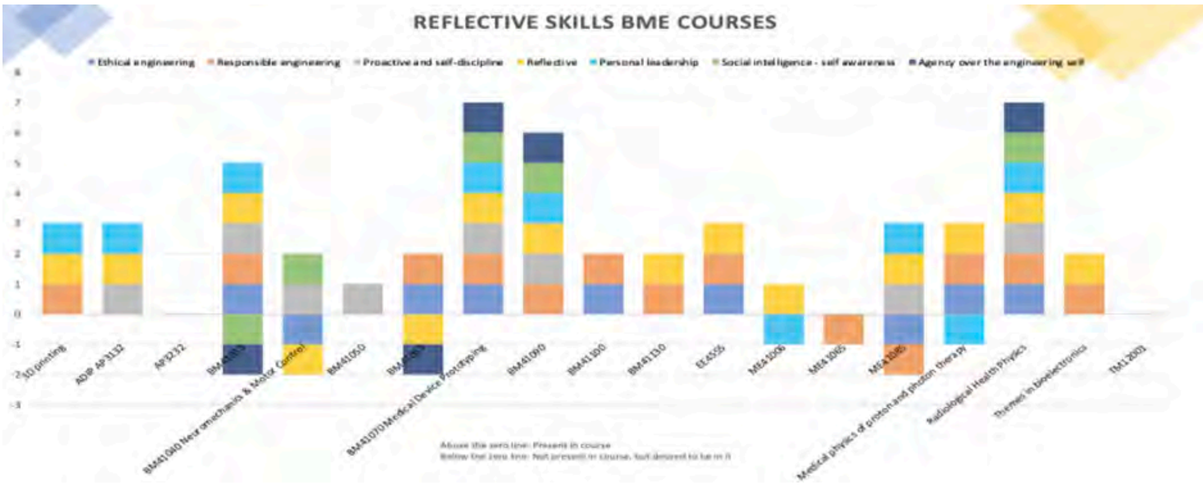
05 Studying in an ecosystem learning environment- (socialisation) requires the students to operate in contextualised environments in interaction with the world (stakeholders in organisations, businesses, and citizens. Therefore, students need informed visions, critical thinking skills and evaluative judgment to assess how to operate in the ecosystem (Spencer-Keyse et al., 2019).

06 Exchanging insights and experiences – the joint dialogue at different levels about pertinent topics are crucial to socialisation, including peer feedback, outside professional involvement, and group discussion with teachers, mentors and guests (Goggins et al., 2022, Diez- Palomar et al., 2020)

Getting the six basic principles into the learning objectives in language that is accessible and provides a joint reference frame allows the teachers to emphasise to students the need for specific skills training. The credit structure can support it and provide an overview of the skills growth within a specific principle. A reflection portfolio and the continuous looped learning that will occur through reflection will allow students to adapt better to different work contexts. Working group dynamics, debates and peer reviews should support students in innovating and changing future practice. Alternatively, after the workshop, more attention can be paid to creating a dashboard summary and enhancing reflection on the professional transition in the workforce.

4 RESULTS TEACHER QUESTIONNAIRE: EMBEDDING SKILLS IN THE CURRICULUM

The second part of mapping the opportunities for change in the curriculum along the framework while making use of the guiding principles was to find out the already used skills in the curriculum. We have used a questionnaire to investigate the knowledge and skills distribution present in each tiers of Fig. 1. The questionnaire on skills included in the courses shows skills in coloured blocks representing the different skills and, at the bottom, the different courses in the curriculum. The questions (1) What do you already address in your course and (2) What is not yet used in your course are depicted above (used) and below (not used) the zero line in Fig. 4,5, and 6. What might be used is not represented



in the graphs.

Fig. 4. Reflective skills

In Figure 4, reflective engineering skills such as responsible and ethical engineering, social intelligence and awareness, proactivity and self-discipline, agency and personal leadership, and reflection skills have been asked. The graph shows that, for example, agency training only occurs in three courses with a particular design focus. (prototyping/ health physics and BME 41). The other teachers need to include this reflective skill in their courses or know if they do or do not. However, responsible, and ethical skills are included in 11 and 12 courses, respectively.

Furthermore, one course, for example, has only one reflective skill included self-discipline; the other skills are not named, as in not occurring in the course, which makes one wonder. A few more courses have this exact visualisation. Do the teachers not know what skills are addressed in their course? Do they not understand what is being asked? Do they address it, but do they not assess it? Do they only do it a little? The results were a reason to engage the teachers in a more elaborate discussion

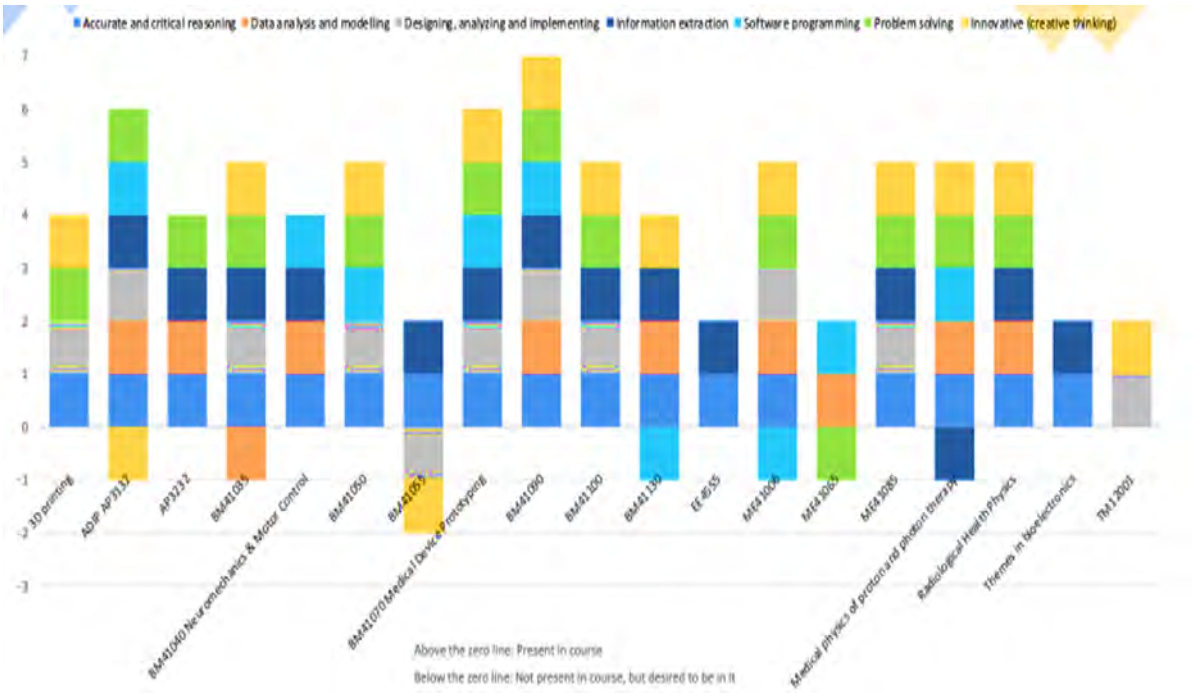


Fig. 5. Engineering skills

In Fig. 5, the Engineering skills are somewhat better recognised. Eighteen out of nineteen of the courses address accurate and critical reasoning. Information extraction happens in thirteen courses. Twelve out of nineteen address problem-solving skills and innovation (creative thinking). In ten courses, design, analysis, and implementation occur. Data analysis and modelling are not necessarily together with software programming in nine courses.

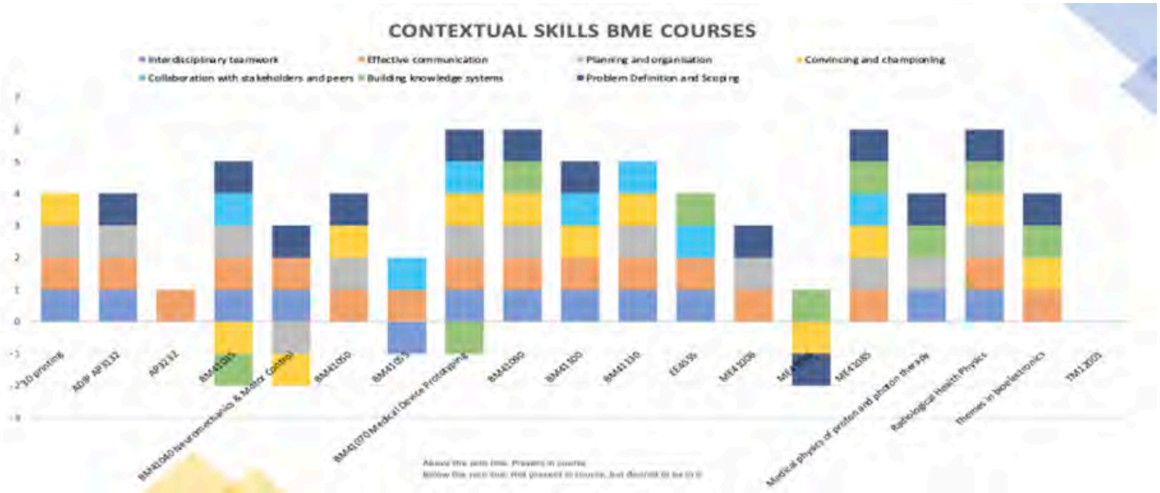

Fig. 6. Contextual skills

Figure 6 represents Contextual skills acquistion, for example, twelve courses address problem definition and scoping skills. Surprisingly, these only sometimes occur together in the same courses where problem-solving is addressed. In eleven courses interdisciplinary teamwork occurs, of which only six also address engagement with stakeholders and peers. Whereas one would expect this to be more equal, doing interdisciplinarity assumes teamwork and stakeholder involvement and contribution to external knowledge systems. Only seven courses contribute to external knowledge systems or disciplinary knowledge building. These are, again, different courses. To make sense of these outcomes, we need some serious, cross-tabular mapping in which the nature of the courses is also addressed and a follow-up conversation with the teachers about interpreting the results.

In a follow-up workshop in discussion with the lecturers, it appeared that not everyone had equally understood the explanation of the skills and their definitions, making the results difficult to interpret. Nevertheless, the next step is to reformulate learning objectives and recalibrate if, when and where the desired knowledge and skills are addressed in the curriculum.

5 CONCLUSIONS

This paper discusses a few design-based steps that may change the Master Programme BME with minimum interventions according to the six guiding principles explained in the results section. This approach has been chosen to alleviate the high work pressure on teaching staff and the fact that Covid-19 has seriously impacted the teachers' well-being. Teachers have been open to discussion and making the best of it. However, it was only sometimes easy to take them along this ongoing road of change and provide them with much-needed ownership to adapt to a new framework. We have had valuable discussions with teachers, resulting in constructive collaborations to press forward towards a new master curriculum slowly. From students' surveys reported elsewhere, we found a positive impact on student's professional capabilities, particularly in personal development (Klaassen et al., 2022). However, much must be done to achieve a more persistent and sustainable change.

6 DISCUSSION AND LIMITATIONS

In this hands-on design-based study, we have provided insight into a design-based approach towards curricular change. The development of a road- map proved to be a suitable means for calibrating opinions and alignment of reference frames. On the other hand, the survey provided ambiguous data that could not be clearly interpreted and needed follow up.

Each step in this process included a double diamond approach, from brainstorming new elements to bringing them back to the curriculum, sharing activities and interpretation, to converging towards one meaning and interpretation. Therefore, these steps have been used for a resocialisation process into engineering education and re-establishing teacher identity for the future, more than anything else.

ABSTRACT

When an important course *Entrepreneurship and Innovation* is cancelled, it is still possible to incorporate innovation into the programme and provide students with opportunities to enhance their specific academic skills. This contribution addresses how the innovation activities have been implemented in two bachelor programmes in computer science at Kristianstad University in Sweden.

The survey results shows that the students wish for the university to continue offering these innovation modules and that they encounter similar modules in upcoming courses. The students felt that the module increased their understanding of the subject and their perception of their own skills.

1 INTRODUCTION

The goal of the innovation activities is to equip students with essential skills and abilities like developing technical and analytical skills, communication, collaboration, problem-solving, critical thinking, and creativity to prepare them in their professional role, to actively contribute to their workplace and work to identify and find innovative solutions to societal challenges.

How can these skills be effectively integrated into the programme(s) in the absence of a dedicated course?

To achieve this goal, the programmes provide project-based learning to enhance the learning experience for students and, additionally, include the events like *Imagine* or *Hackathon*, where students work in teams to develop innovative solutions to complex problems. *Imagine* event provides an opportunity for students to showcase their skills and creativity and receive feedback from experts in the field. It is offered at Kristianstad University several times a year with different focus areas linked to the University's profile area of environment, health and water, which for computer science students give a chance to work interdisciplinary. *Hackathon* event is provided by older students and the goal is to challenge and encourage younger students in programming.

By providing students with practical experiences and exposure to modern technologies and teaching methodologies, the programme prepares them to navigate the ever-changing demands of the workforce. The incorporation of team-based learning and events enhances students' collaboration and creativity, providing them with the skills (effective communication, leadership, project management) they need to succeed in the modern workplace.

1.1 Innovation

Many definitions and interpretations of innovation are used in different contexts and disciplines. The most widely accepted definition of innovation is described in the Oslo Manual [1] as:

> *"An innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organisational method in business practices, workplace organisation or external relations."*

([1], line 146, p.46)

Baregheh et al. [2] present a comprehensive study based on comparison of 60 definitions of innovation collected from various disciplines. Based on that they propose a following diagrammatic definition:

> *"Innovation is the multi-stage process whereby organizations transform ideas into new/improved products, service or processes, in order to advance, compete and differentiate themselves successfully in their marketplace."* [2]

The definition of innovation presented by Baregheh et al. [2] is most relevant to computer science students because of its "multi-stage process" as well as it emphasizes the importance of transforming ideas into new or improved products, services, or processes. This aligns with the goals of many projects and students' activities as HackaThon and Imagine (described below), which involve creating new software or to meet user needs or solve problems.

1.2 Hackathon

A hackathon is an event, usually over a short time such as 24 or 48 hours, where programmers, developers, designers, and other technology enthusiasts engage in rapid and collaborative engineering, typically in a competitive setting. Participants work in teams to create solutions for specific challenges or to develop innovative applications, often with a focus on a particular theme or goal. The goal of a hackathon is to encourage creativity, innovation, and collaboration among participants, and to produce a functional prototype or finished product by the end of the event. Hackathons can be organized by companies, educational institutions, government agencies, or other groups, and are a popular way to promote technology education, entrepreneurship, and innovation.

1.3 Background

Kristianstad University is a small but dynamic university that strives to be among the most attractive universities in Sweden. The university's goal is to strengthen its reputation as a high employability for students and gain recognition outside of Sweden. To achieve this, the university has implemented various measures such as worked-based teaching across all programs and internationalization, which includes, among other things, adapting programs to student and teacher exchange. In addition, the university has established academic tracks, sustainable development, gender equality and innovation.

To comply with the university goals, the computer science programmes are revised around every three years. Students, alumni as well as the companies have a big impact in these revisions.

1.3.1 Entrepreneurship and Innovation (2011 – 2022)

The course Entrepreneurship (IE520A) was introduced for the 3rd year computer science students back in 2011 because of a revising the programmes with adaptation to the university’s vision. In 2015 the course has been revised by adaptation of Innovation (Entrepreneurship and Innovation, IE300A). This course was taught until 2022 with small revisions (IE301C)[1]. Unfortunately, with new revision and more focus on computer science, the course was cancelled. However, innovation part became implemented in new programmes in a new way – as an innovation track.

The main question was whether and how it is possible to incorporate innovation into the programme when a course *Entrepreneurship and Innovation* was discontinued. What should be included and excluded.

[1] Course syllabus - Entrepreneurship and Innovation - 7,5 credits - IE301C , English | HKR.se

1.4 Related work

Innovation at higher education brings also different views. In OECD Report from 2016 [3] can we find outcomes of different projects, like “Innovation Strategy for Education and Training”, “Innovative Learning Environments”, and “Open Education Resources”. Here the focus lies on innovation / digital technology for learning, e.g. innovative pedagogic models; simulations as a low-cost access to experimental learning; e-learning; international collaborations; as well as for implementing and evaluating innovation in the education system.

Hoidn et al. [4] review the effectiveness of problem-based learning (PBL) compared with traditional approaches in higher education teaching for developing skills for innovation. The report explores the extent to which PBL can develop discipline-specific and transferable skills for innovation like social and behavioural skills such as motivation, interest, self-confidence, self-directed learning and teamwork.

Kumar et al. [5] discuss how educators straggle to improve, re-invent existing courses, re-organize majors and carve out new majors. The authors present in short some of the innovations that have been introduced into the undergraduate Computer Science curriculum. In most cases the students do groups activities and/or projects.

Daimi and Rayess [6] shows an importance of Entrepreneurship course in the curricula of Computer Science and Software Engineering education. They motivate that “computational thinking will govern the process of innovation to produce new software products and technologies, and entrepreneurial thinking will establish the foundations for marketing these products and technologies.” The authors introduce a design of a software entrepreneurship course, its rationale, description, objectives, outcomes, assessment and present case studies and projects. The goal of the course is to bridge the gap between creating products and creating marketing opportunities.

Zhang and Dong [7] present a need of innovation in teaching in China as three aspects: “teaching reform, training system and a platform for industry-university-research cooperative education”.

To consider innovation as a process, it is crucial to provide training to students from their first course, and it is equally important to engage and motivate them right from the start. An interesting study about the engagement of first-year students in large courses during the covid-19 was done at Swedish university [8]. It explores two successful cases of how active learning, togetherness and engagement can be created. The authors experienced that the students had actively participated in the arranged activities and the course passing rate was higher compared with the face-to-face teaching. The course evaluation also showed that the students were satisfied with course contents and various course activities.

2 METHODOLOGY

2.1 Action Research

Implementation of innovation activities is based on the action research (see Fig. 3) where a group of teachers involved in it discuss and improve the process in regular meetings.

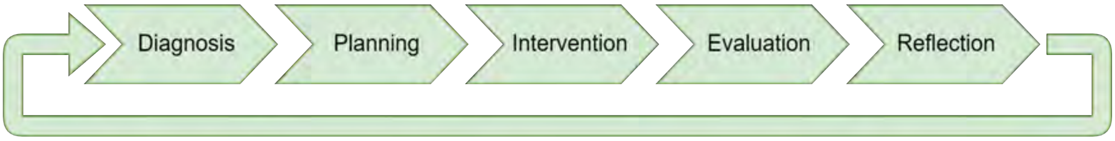

Fig. 3. The cycle of five stages in action reseach. [9]

2.2 Survey

At the end of the course that was held in Spring term of 2023, a survey was distributed to the students. 45 out of the 60 participating students responded.

3 STRUCTURE OF COMPUTER SCIENCE PROGRAMMES WITN INNOVATION TRACK

The following figures (Fig.1, Fig.2) show two computer science (CS) programmes with marked courses that includes innovation activities. The courses marked with the dots are the courses where including innovation aspects is optional. In both programmes, the marked courses include the individual or group projects.

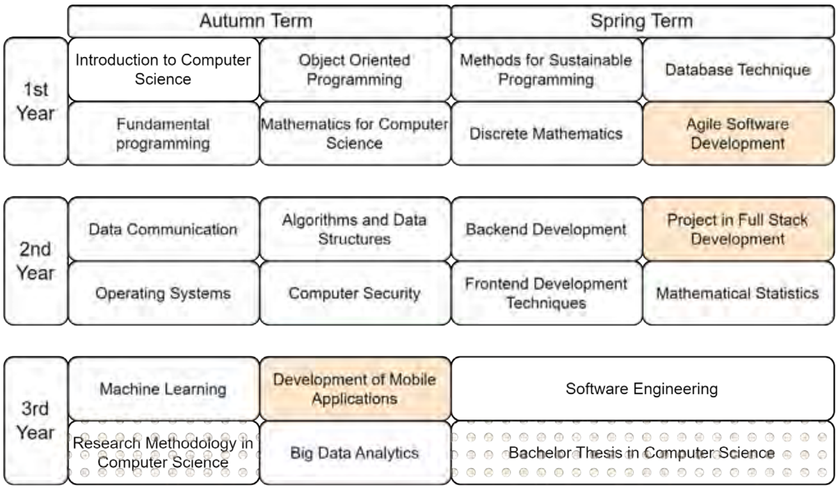

Fig. 1. Bachelor Programme in Software Development[2]

[2] Programme syllabus - Bachelor Programme in Software Development - TBSE2 , English | HKR.se

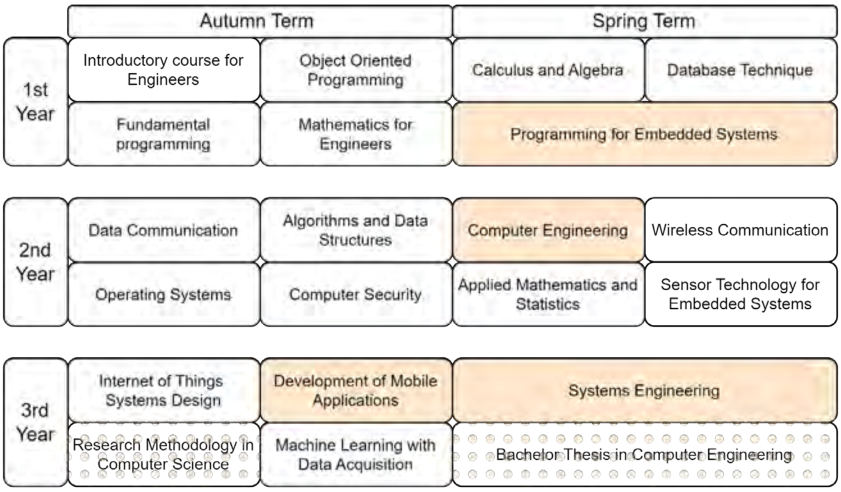

Fig. 2. Bachelor Programme in Computer Science and Engineering, Specialization in the Internet of Things[3]

3.1 Development of Mobile Applications course, DA324A[4]

The course Development of Mobile Applications is offered to both programmes. It includes lectures, labs, and a group project. The aim with the course is to teach students Android development and how to apply that knowledge to real-world problems. During the project work, students are expected to utilize their innovative skills to create Android applications that are useful for society.

The project work is conducted in collaboration with the university's department, which primarily focuses on connecting the university with society through an event/workshop called ***Imagine***[5]. All programmes offered by the university are eligible to participate in the Imagine workshop, which means that there are many innovative areas with various issues that university students can work on.

At the Imagine workshop, one representative from a company joins a student group to collaborate on designing features that would address a particular issue faced by the company or society. However, it is also possible for representatives from other area of society, such as hospital personnel, to contribute by presenting and discussing issues in their respective environments. In this way, students can work to find innovative solutions to a variety of challenges.

The following are some examples of Android applications developed based on the issues presented during Imagine event:

- In 2018, computer science students joined Imagine workshop with nursing students to come up with innovative solutions for hospital care[6]. The collaboration resulted in the

[6] Datavetare ger draghjälp på ToY Imagine | HKR.se (in Swedish)

development of several various applications, and an example of one such application can be found here[7]

- Despite the pandemic, the Imagine workshop was successfully conducted online[8].
- The workshop held this year involved both of our data science programs and included 12 companies with 15 app ideas or questions. The quality project was completed by 15 student groups, each comprising four students, who developed a mobile application as part of their coursework.[9]

3.2 Systems Engineering course, DT337A[10]

The Systems Engineering course is the second and last project course in the Engineering curriculum. This course is conducted concurrently with the thesis, and the students work on the same project in both courses but focusing on different aspects. In the thesis course, the emphasis is on the scientific part, while the systems engineering course focuses on prototype development. This construction allows the students enough time to develop an innovative prototype as well as evaluate it within the thesis. The prototype development project involves both hardware and software aspects. The students have the possibility to work on the project in an industry as well as working by themselves at the university. Both industry projects and independent students' projects are often innovative.

Examples of projects include:

- Smart heating control: This prototype is used to control heat to the facilities by an actuator and measure system temperatures. The method used to control the system was a deep learning model implemented in the prototype edge device classifying the system's different behaviours, preheating, heating and cool down. The prototype was installed in a real house and evaluated for several weeks.
- Preventing mould damage in attics: This prototype notifies property owners when environmental conditions in attics are favourable for mould growth. It was tested on site in an attic.

3.3 Other examples of engaging students

3.3.1 HackaThon at HKR. 12th of November 2022, Saturday, 14:00 – 18:00.

This hackathon was organized by senior CS students and took place on campus and online. The event was aimed at all CS students. The tasks were adapted so that everyone could do at least one task. Students started with an easy task and slowly progressed to more difficult ones. All the tasks were designed by a senior student, who described the experience as "a great learning opportunity for me." The students could participate individually or in groups and could choose any programming language. The invitation letter encourages first-year students not to be intimidated by

[10] Course syllabus - Systems Engineering - 15 credits - DT337A , English | HKR.se

difficult tasks, but to view them as opportunities to solve creative challenges and learn from the experience.

Senior students described the hackathon as a social coding event that brought students together to solve coding tasks. The level of experience didn't matter, the focus was mostly on having fun and challenging themselves with like-minded people.

Feedback from the 1st year student: “The hackathon was fun and gave me insight on how to think in different ways regarding coding. And I gained a lot of experience from solving the different tasks. I did learn how even in a team we had our own ways of thinking and coding to reach the result.” Feedback from the senior student: “I think it was a successful event just like the year before. […] Those who participated truly enjoyed it and thanked us for getting to have this opportunity to not only experience working in teams but also getting to try more challenging tasks with their knowledge. Most participants were first year students, and we helped some who asked for help to think through the problems in different ways to find the way towards a solution.”

3.3.2 The FoodHack. 13-15th of March 2023, Monday – Wednesday, Krinova[11]

The Food Hack[12] is a 48-hour long innovation competition and food conference for the global food community initiated by Krinova. This year’s Food Hack theme was on Data-Driven Food System[13]. The goal was to explore the opportunities of data as an underutilized tool within the food and agriculture sector. During the first day the participants were invited to three talks: “Tech and data driven food system – what it means and how will it change what we eat and grow”, “How data is transforming agriculture”, and “Helping the consumer care about food”. Thereafter, the participants worked in teams to set up projects boosted by the latest research and experienced mentors, all in the spirit of challenge-driven open innovation.

Admission to Food Hack was free, and all meals to nourish the mind were included from Monday lunch until Wednesday lunch, along with accommodation in dorms (participants were required to bring their own sleeping mat and bedroll). The best hack-teams had the opportunity to win prizes worth 50,000 SEK.

Feedback from one student: “I totally recommend this experience. I think that you only not will gain new knowledge, but also friends. The tutors are amazing. It’s people that inspires you. A new experience, I recommend. Thank you.”

3.3.3 Other events

The University and the Computer Science department offer students additional events throughout the academic year, such as the Future Fair, Research Day at CS, and Career Fair. These events provide students opportunities to kick-start their job

[11] About us - Krinova - Krinova

[12] Food Hack – By Krinova

[13] Food Hack by Krinova 2023 - YouTube

search, establish connections with potential employers, and discover topics for course projects and their degree thesis.

4 RESULTS - SURVEY

The survey shows that the students wish for the university to continue with this module (6.1 in average on a 7-point scale) and that they encounter similar modules in upcoming courses (5.5). The students felt that the module increased their understanding of the subject (5.7) and their perception of their own skills (5.8).

The students reported being motivated and engaged in the course module. After analyzing the survey results, we believe that the reason for the success was the students´ collaboration with companies on real-world tasks, which were inherently engaging and stimulating. In addition to programming the application and utilizing technical knowledge they had acquired throughout their years in the program, the students also acted as consultants, which is a role that many of them will hold in their future careers. This experience helped strengthen the bridge between academic studies and professional work. Two particularly positive outcomes emerged from the course module: one of the actors purchased the prototype app that the students had built, and another actor will be using the prototype app in a research project.

The students not only received grades in Android programming, but also gained knowledge in meeting the customer, maintaining contact with the customer, and acting as consultants, which is a valuable addition to their resumes.

One wish and hope from the teaching staff was that the students would continue with their business projects in subsequent degree projects. One group made this choice and continued developing, investigation and evaluation as a degree thesis, where the company stayed as a secondary supervisor. Their product is currently in use.

5 SUMMARY

Even if an important course *Entrepreneurship and Innovation* was cancelled, it was still possible to incorporate innovation into the programme and provide students with opportunities to enhance their specific academic skills. The examples show how students´ creativity develops through their studies. Nevertheless, the entrepreneurship part is missing from the programme. On the other hand, Krinova offers and helps students an opportunity to do start up their own business.

Keywords: *Computer Science, Academic and Sustainable development tracks*

ABSTRACT

The 3-year Bachelor Programme in Software Development study program at Kristianstad University, Sweden, aims to integrate not only academic competencies and skills in subject courses but also critical thinking skills on how Computer Science can contribute to achieving the sustainable development goals.

Starting from an understanding of the sustainable development goals, students begin a process of designing and implementing applications for some specific goals. Through participation in various activities, students exchange the ideas and perspectives, and are challenged to consider multiple solutions to complex problems.

The students' critical thinking, communicative abilities, and the ability to solve problems both individually as in groups are developed in a clear progression through the education.

This contribution aims to provide an overview of the sustainable development track in the programme, as well as in-depth presentations of some of the courses covered. The main objective of the study was to gather students' perspectives and feedback on the relevance and importance of sustainable development goals in the context of computer science. Students’ views have been evaluated through the survey.

1 INTRODUCTION

This study presents an overview of the sustainable development track within the Software Development program as well as detailed insights into selected courses. Furthermore, students´ perspectives has been conducted and evaluated via a survey.

1.1 Background

The Bachelor Program in Software Development at Kristianstad University, Sweden, is three years programme and is provided for both national (Swedish) and international students. In addition to preparing the students to further studies, the university aims to ensure that they become highly employable. To achieve this goal, several changes in the programme have been implemented during last 10 years.

A main revision of the program was made during 2013-2014 where the Computer Science department has been a member of the CDIO initiative [1] and the program was organized according to the principles of the CDIO initiative. Connections to the industry were achieved in the program through work-based education and "design-build-test" - projects integrated in the subject and project courses. Further changes were made to the program like a clear progression between the courses (e.g., mathematics, programming and software development skills) as well as a progression in academic skills. The implementation of academic skills has been named the *academic track* [2]. It is a systematic development of general competences that create important prerequisites for the development of the scientific approach, which in turn led the students being able to assimilate the subject-specific and reach the degree goal of the education. The academic track thus became a tool that created a clear connection between the general and the subject-specific. In Spring 2018, employees from Computer Science department participated in the university pedagogic course "Teaching for sustainable development". As a result, the subject of “sustainable development” was implemented to the programme in Autumn 2018. Integrating *sustainable development track* in the program was created in similar method as when integrating the *academic track*. New revision of the program was done in 2020 by implementing applied computer science with machine learning and a new course "Research methodology in computer science" to ensure research connection and raise students' scientific attitudes as well as prepare students for the bachelor thesis. The current version of the programme with sustainable track is presented in Section 3.

1.2 Literature Review

The integration of SDGs in computer science education is widely discussed around the world. Nwankwo et al. [3] present six various areas in which CSE (Computer Science Education) and ICT (Information and Communications Technology) are applied for sustainable development. They point the challenges and barriers of the deployment of ICT solutions towards the realization of SDG in higher education and technology development in Nigeria. Gordon [4] describes how the four priority ideas identified by the UK government can be integrated into higher education in computer science. The author gives the examples of the topics that provide opportunities for discussion in the classroom, e.g., the practical and ethical aspects of computer use, consider pros and cons from a societal perspective, security aspects, etc. Argento et al. [5] present how academics representing different disciplines, with specific traditions and characteristics, face the sustainability challenge. The case of University in Sweden illustrates the experiences shared by six colleagues, representing different disciplines (inclusive computer science), engaged in implementing sustainability in their courses and programmes. Mawonde et.al [6] show a case study of the University of South Africa from the distance education perspective. The research revealed several practices that align with SDGs in teaching, research, community engagement and campus operations management. Fisher et.al [7] survey the integration of environmental and societal sustainability into computer science curricula at colleges and universities around the world. They present two integration levels: the course-level, where the computer science courses focus on topics at the intersection of computing and sustainability, and the component-level, where the sustainability themes are introduced as the course components, such as lectures, exercises, and projects. Further, the authors speculate on the future of sustainability-themed computer science education, including curriculum-level integration. Here, they talk about a specialized track with courses within the track differentiated by sustainability topics. They think that computational sustainability majors will be designed around frameworks of evidence-based decision making.

2 METHODOLOGY

2.1 Action Research

Creating and implementation of academic and sustainable development tracks is based on the action research (see Fig. 1) where a group of teachers involved in it discuss and improve the process in regular meetings.

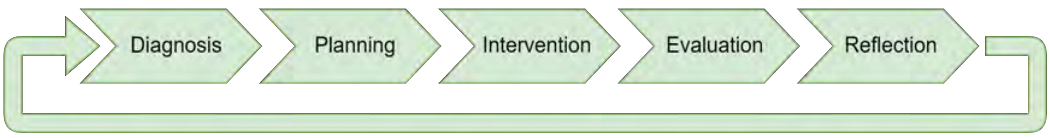

Fig. 1. The cycle of five stages in action reseach [8].

2.2 Survey

The survey was conducted in the Spring term 2023 for 1st year students that already had two courses involved in sustainability track. Students were asked if they were familiar with the subject of SDG (sustainable development goals) before joining the university and their thoughts on SDG in relation to CS (computer science) programme as the amount of information included in these two courses.

3 OVERVIEW OF SUSTAINABLE DEVELOPMENT TRACK

Fig. 2 presents the current version of the programme. The sustainable development track comprises five courses: one introductory course and four project courses. Yellow-marked courses belong already to the track while the green-marked course (a new one in the programme) is under reconstruction to be also applied in the track. Additionally, there is a final course in the program, the bachelor thesis, which allows students to choose a sustainability aspect, although it is optional. However, reflection on societal and ethical aspects in the thesis is mandatory.

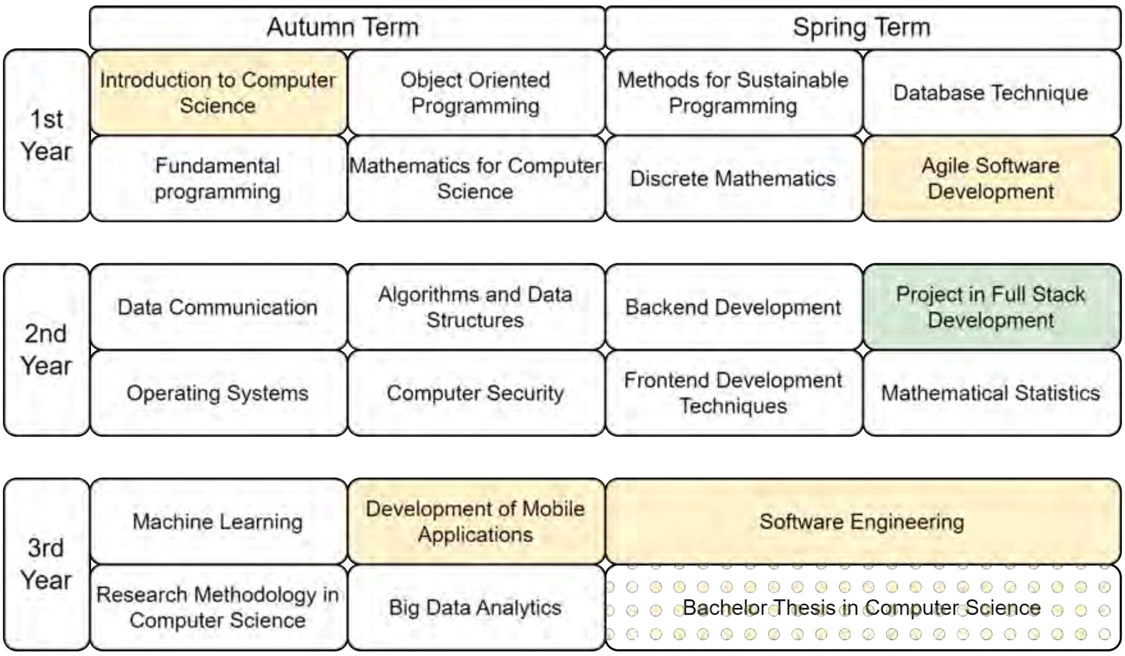

Fig. 2. Bachelor Programme in Software Development, HKR[1]. Marked courses are the parts of the sustainable track.

Table 1 presents an overview of the moments in the courses that include sustainability aspects, along with information about students' work and examinations. It also indicates which learning outcomes are included in the course syllabus that covers the sustainable development track.

[1] Programme syllabus - Bachelor Programme in Software Development - TBSE2 , English | HKR.se

Table 1. Sustainability track in details

Course	Moment in the course	Students` work / examination	Learning outcome(s)
Introduction to Computer Science	Guest lectures: AI in computer science; AI for Sustainability; SDG and Ethical aspects; Literature search; Academic writing; Peer review;	Individual academic report on the subject: “AI in research with a focus on SDG and Ethical Aspects” Practice reviewing each other's reports; Individual presentation and discussion in group during the seminar.	- be able to make simpler assessments with regard to relevant social and ethical aspects (10)
Agile Development Methods	Presentation techniques; Projects.	Group projects with individual written and oral presentations.	- critically examine and reflect on his or her own skills in computer science according to the UN Global Sustainable Development Goals (9)
Project in Full Stack Development	Projects.	Individual written and oral presentation and group project.	Under reconstruction
Development of Mobile Applications	Projects, Imagine workshop	Group projects with individual written and oral presentations.	- discuss the social and ethical issues that may be raised by the use of mobile applications (11) - identify needs for further knowledge and competence for the development of mobile applications (13)
Software Engineering	The project work is in the form of work with company(-ies).	Individual oral presentations and an individual written report.	- demonstrate the ability to make judgements in software projects taking into account relevant scientific, societal and ethical aspects, and demonstrate awareness of ethical aspects of research

			and development work (12)
Bachelor Thesis	An independent project as a specialised study in computer science. (in pairs or individually as determined by the examiner)	Research, written report, oral presentation, written and oral public opposition on another degree project.	- be able to make assessments with regard to relevant scientific, societal and ethical aspects within the field of computer science (6)

4 EXAMPLES OF THE EXAMINATIONS AND PROJECTS FROM SOME COURSES

4.1 Introduction to Computer Science, DA100D

Introduction to Computer Science[2] is the first course that the 1st year Software Development students meet during their education. The course covers a broad knowledge in computer science and equips students with essential academic and scientific skills required for their studies. Additionally, the course provides insight into ethical aspects from a software developer´s perspective and offers a perspective on applied computer science. The students work individually and in groups. Topic of the individual report is “AI in research with a focus on SDG and Ethical Aspects”. Some of the interesting subjects covered in the reports include:

- *Food Waste & AI in SDG efficient production.*
- *AI Implementation in Surgery with an eye on SDGs and ethical considerations.*
- *AI in smart cities. With focus on SDGs and Ethical Aspects.*
- *Role of A.I in Education. Online Teaching and Learning.*
- *The future of humans in an AI-dominated world – with a focus on SDGs and Ethics.*
- *AI´s Fight against world hunger.*
- *Water treatment the environment and the ethical implications.*

It is worth to mention that the report should follow the academic writing style. Students learn how to do literature search, literature study, how to create research questions, how to use the references (tables, figures, literature) and how to write peer review.

4.2 Agile Development Methods, DA116B

The course Agile Development Methods[3] runs as last course in the first year of the programme with purpose to tie together gained knowledge from previous courses, and to develop basic knowledge in carrying out agile software development projects based on the UN Global Sustainable Development Goals.

[2] Course syllabus - Introduction to Computer Science - 7,5 credits - DA100D , English | HKR.se

[3] Course syllabus - Agile Development Methods - 7,5 credits - DA116B , English | HKR.se

The students are preparing for the project through a series of lectures and seminars, where they work both individually and in groups to learn about the product engineering and how to align their product with SDG 3.4, which focus on mental health. As a result of the project, a wide range of desktop applications were developed, including:

- Journaling mood applications with resulting graph to bring to doctor's appointments.
- An app designed to help individuals manage personal stress that is based on earth ecology issues.
- Applications that focus on specific groups of people, such as students or the elderly, to promote their health,
- Applications with training programs for physical activities to promote mental health[4].

During the project, students take on different roles such as scrum masters (team leaders), developers, testers, and support staff. They switch between these roles during the four sprints, which culminate in project meetings where progress is evaluated. The students work both individually and in groups, with the aim of developing a final product that addresses the mental health issue they have chosen. At the final presentation, the students give an oral presentation on the development of the final product and submit a written report.

4.3 Software Engineering, DA330A

The course Software Engineering[5] primarily aims to train students in working in large-scaled projects, and has during the years undergone several improvements, such as, outlined in ([9]). The student group is divided up into *main groups* of about 15 students, each such group is furthermore split into sub-groups of about 3 students with the aim of fulfilling one specific technical goal of the system as a whole, according to Fig. 3.

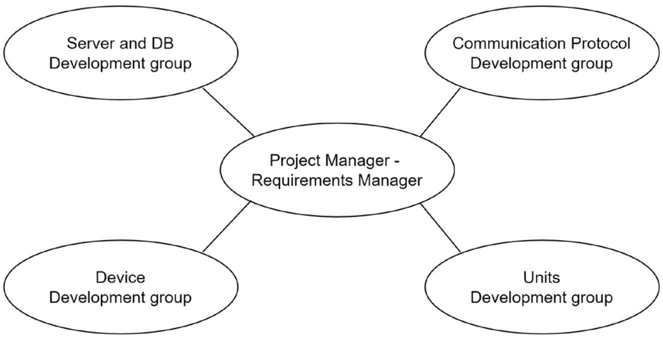

Fig. 3, Student group structure

The main theme of the project under development is to implement a support system for young people with functional disabilities. That approach has its origin in an investigation performed by teachers/researchers of Computer Science at

[4] Myrmidon – appen mot psykisk ohälsa | HKR.se (in Swedish)

[5] Course syllabus - Software Engineering - 15 credits - DA330A , English | HKR.se

Kristianstad University, at a gymnasium for young students with specific needs. The investigation found that the students were dependent on assistance in their living for several banal reasons, such as, turn on lights of lamps, or turn on fans, or pull down blinds to protect against sunshine and warmth in their livings. A consequence of the investigation was an initiation of a Bachelor thesis ([10]) to prototype a smart home-system, where the students should be able to turn on/off lights in their livings.

While that prototype unfortunately did not render further cooperation with the mentioned gymnasium, a consequence was the initiation of a project theme, focusing on Smart Home techniques for young people with functional disabilities. Techniques for supporting such as system is outlined in [11].

The course-students of Software Engineering are aware of that possible stakeholders of the systems are the mentioned gymnasium-students. The course-students should therefore pay respect to the system being supporting the gymnasium-students. As one example, for the course during the spring semester 2023, there is one sub-group that is developing a user interface through an eye-tracker, to support people that are partly paralyzed, and where the eye-tracker is borrowed from an IT-support person at the gymnasium.

The students are furthermore informed about that the system also corresponds to system development to meet SDG 4, on Health and Quality of life. Still, further SDGs that are met by this kind of system are SDG 11 on Sustainable Cities, and SDG 16 on Peace, Justice and Strong Institutions, both addressing the significance in societies being inclusive.

5 RESULTS – SURVEY

37 students participated in the survey. 16 students (43%) were not at all familiar with SDG before joining the University, while 4 students (10%) were a lot familiar with the subject. The overall reaction of applying SDG in CS courses was positive. The answers to the question about the motivation to learn programming through SDG adaptations in CS was very diverse: from 6 (16%) answers “not at all”, through 9 – 12 – 7 in the middle, up to 3 (8%) answers “a lot” (see Fig. 4). The average rating (in scale from 1 to 5) into the integration of SDG in the courses was 77,2%. When asking about the amount of information about SDG covered in particular course, 86% of participants answered: “just enough” for the course “Introduction to Computer Science”, and 89% for the course “Agile Development Methods”. Regarding the relevance of SDG in CS in the future career as software developer, the students were positive giving the average rating of 70,8% (in scale from 1 to 5). Even more positive were they giving the average rating of 81,6% for the question on importance of consideration of ethical and sustainable issues in their work (see Fig. 5). In the open question the students asked about the real-world projects; SDG-focused events such as sustainable tech solutions; collaborations with sustainability organizations. Only one student was very negative about sustainable development, which gives us a thought about some small changes in the first lesson on SDGs and ethical aspects.

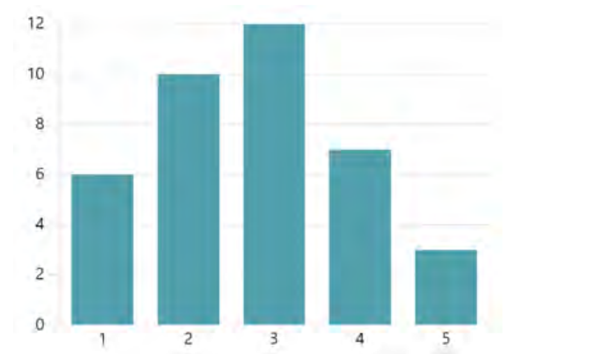

Fig. 4 How much did the SDG subject in CS influence your motivation to learning programming? (1 = not at all, ... 5 = a lot)

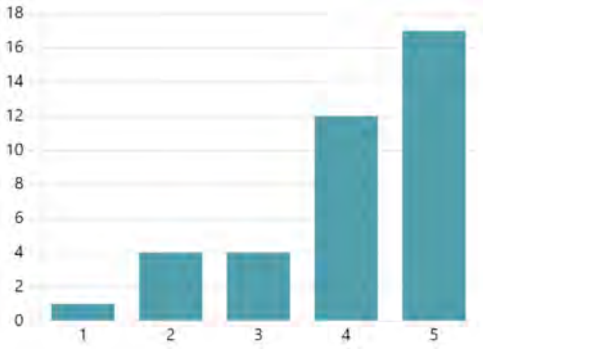

Fig. 5 How important do you think it is for software developers to consider ethical and sustainable issues in their work? (1 = not at all, ... 5 = very important)

6 SUMMARY

Integration of academic and sustainability tracks results, among other things, in high-quality degree theses and more interesting projects with focus on applied computer science. Students write better and can easily connect their reasoning about ethical and sustainable development aspects in the theses and projects. In addition, the students' opinions regarding the implementation of the sustainable development track are quite different, but above all positive. Interesting results were that the students were positive about the importance of the SDG and the consideration of ethical and sustainable issues in their future career as software developers.

Of course, to include sustainability aspects or even academic aspects, something must be skipped in the programme. In our case, we had to exclude some questions/problems that covered pure data science.

The interesting future work would be to ask similar questions to the same students two years after they finished the education.

ABSTRACT

The nuanced nature of engineering as a profession is highlighted in a recent statement by the EPC (2023) in response to the UCAS publication *'The Future of Undergraduate Admissions'* (2023). Focusing on the value of Personal Statements within the University Selection System, the EPC asks UCAS to provide more practical information to prospective students about the nature of engineering and what prerequisite qualifications are needed to study engineering. Such clarity is particularly important when considering Engineering Degree Apprentices.

Starting with the research question "*How can the gap between school and university be bridged in engineering education?"* the paper critically discusses a project currently being undertaken by a multi-disciplinary team of colleagues working together to enhance the student experience.

Located in one the UK's largest Engineering Education Departments, the "Step Up" Project analyses the barriers and drivers to engineering education faced by first-year Degree Apprenticeship students from three distinctive engineering and computing science disciplines. This paper represents a small part of a much larger project where

the student experience is being prioritised and high-quality learning and teaching is expected. The paper is built upon the emergent findings of a three focus groups with engineering degree apprentices. Whilst the findings are relevant to all years of study, the recommendations and conclusion highlight the importance of 'getting the first year right' and empowering students to 'step up to success' in university and in work. This evidences a demand for clearer explanations of the knowledge and skills expected of incoming students

1. INTRODUCTION

Building on the corpus of knowledge relating to the first-year engineering student experience (Andrews et al., 2019; Daniels, 2022), this paper sets out to provide a unique insight into engineering degree apprenticeship students' reflections of the main issues impacting their studies as they near the end of their first year of study.

Starting with the research question "*How can the gap between school and university bridged in engineering education?"* the paper discusses the emergent findings of an ongoing pedagogical research project which examines engineering students' perspectives of studying at WMG. The primary objective of the study is to inform and influence academic practice and pedagogy, thus enhancing the student experience from the first year onwards.

2. STUDY APPROACH

The part of the study referred to in this paper provides an insight into the emergent findings of three focus groups were conducted with fulltime degree apprenticeship students in the last academic year. With a sample size of 55 students, focus groups were conducted 'live' online using Miro as a research tool. The data was contemporaneously recorded onto Miro before being transferred into MS Word. Concurrently, contemporaneous notes were made. The decision was taken not to record any demographic details of the students to assure confidentiality. Once the interviews were concluded the data was analysed following phenomenological techniques whereupon it was coded and classified into six distinctive but interlinked themes: Dualistic Education – Balancing Work and Learning: Assessment & Timetabling: Pedagogy & Practice: Academic Integrity: Groupwork: Relevant Engineering Education.

The following paragraphs provide a detailed overview of the conceptual analysis of qualitative findings of the study, providing a distinctive insight into the engineering apprentice student voice. From there the findings are critically discussed before providing a brief overview of ongoing changes to how education is being provided within WMG.

3. THE STUDY FINDINGS

3.1 Dualistic Education: Balancing Work & Learning

One of the key issues to arise out of the study is unique to the 'apprenticeship' programme in that some of the students felt the training received in the workplace did not adequately equip them with the level of knowledge and skills needed to succeed in the classroom:

The WMG course [faculty] assume our line managers / teams will deliver on the technical development … … . When this isn't the case, it leaves students in an awkward predicament of having to try and force a move to a team that suits their career aspirations

From the university perspective the course has been fine. However, from [an employment] perspective the process of ensuring students have enough technical development has not been fully delivered

The resultant misalignment of skills and knowledge between work and study impacted the students in a range of different ways. For many, it resulted in a level of anxiety, something that became evident during the assessments:

[One technical] assignment was very stressful for someone that doesn't have enough experience to create a whole web app. Considering the difficulty of the task the deadline was way too short

The assignment on web development, with little experience was highly stressful. It was covered in the lectures but again expected prior experience at work…

On a more positive note, some students suggested that the gap between work and university was covered by the interdisciplinary nature of the learning and training received:

Modules contain useful information; whilst they do not directly relate to [the type of engineering I am studying], they are useful in a business context.

The course is good as it is a mixture of different engineering skills, IT, and business.

The mixture of 'harder' engineering skills, 'transferable' professional abilities, and 'softer' business competencies is not unique to apprenticeship training. However, the intertwined manner in which each of these is embedded as part of apprenticeship courses, with a mix of different influences, priorities and a need to meet employer expectations means that first year engineering apprentices have to quickly adapt to their dualistic role. The impact on learning that being caught in the middle of work and university has on apprenticeship students is not yet fully understood. One of the areas which the first years in this small study did discuss was, however, assessment – where the delicate balance between what is taught in the classroom and what is learned in the workplace was again identified as an issue.

3.2 Assessment & Timetabling

Assessment was mentioned by all of the students. For some of the first-year students the main issues related to the timing of the assignments and what was taught in the module. Perhaps a causal symptom of low levels of independent learning skills possessed by students as they enter university, the first years perceived assignment briefs to lack clarity; something which they identified as causing undue stress:

Unclear assignment briefs with a lack of clarity get in the way.

Particularly when things are changed close to the deadlines

Assignment briefs and ambiguous briefs make the assignments more stressful than they need to be

It is not unusual for first year students to bemoan the fact that they are not taught all of the course content in the classroom. Although for apprenticeship students the issue isn't simply about a lack of independent learning skills, but instead relates back to the first theme discussed in this paper, differing expectations of faculty and students and a misalignment between what is taught in the classroom and learned in the workplace.

3.3 Pedagogical Approaches in Engineering Education

The study took place after the pandemic whereby the majority of students interviewed had spent at least 18 months in lockdown learning at home and online. When the interviews took place students were divided more or less equally when it came to whether they preferred online or face-to-face teaching. Some students asked for a choice in whether they should attend a lecture in person or not:

It should be a choice as to go on site for face-to-face lectures or not. We should be told what the lecture is about in advance so we can make an informed decision

I'd like the option to study at home rather than have to be in person

3.4 Academic Integrity

Like the majority of first-year students many of the apprentices struggled with referencing and academic writing, particularly at the beginning of their course. One student mentioned the penalties associated with poor academic practice:

I have been marked down for incorrect referencing, despite having my referencing checked by someone qualified and being told it was correct.

Others' indicated that they felt it was their lecturers responsibility to provide them with a list of academic sources, which suggests a lack of preparedness for independent study:

The reference list at the end of the slides is often wrong. They're the same in every session in the module [ ]. Sometimes the references don't relate to the content of the slides

Adding a citation on every slide would be super useful. Often, we need to use information from the slides in our assignments and a topic can be too generic to google.

3.5 Groupwork

Like the majority of students, engineering apprentices report negative experiences around working in a group:

Group projects don't tend to work as there will always be 50% of the group who won't work and who will get away with this. There's no way to rectify this. The fix is individual assignments.

Randomised groups for some coursework where the lectures decide the groups. This causes problems when people have different work ethics.

Group projects are more irritating than beneficial, they lead to conflict and greatly affect wellbeing as people think they can get away without working. This is something that has greatly impacted my opinion of the course.

The most concerning remark about groupwork came from a student who questioned the academic validity of this type of assessment:

Group projects seem to be giving lecturers less to mark – doesn't benefit us as students really especially when they are randomised - being with people who don't work as hard is so frustrating when you care about your grades

Conversely, two students suggested that for them, group working was a positive experience: '

Groups allocated by the lecturer are useful and give everybody a fair chance (i.e., no higher chance of being with a 'better' group)

Group projects keep me going when I've been in a group with people who want to get the same grade as me

3.6 Relevant Engineering Education

As they neared the end of their first year, the students commented about the gap between university and work with one student indicated that the issue was with who, from the employer, contributed to the design of the curriculum:

The course is clearly designed by / with [the employers] – but it seems to be designed by high level managers, not the low-level managers who actually, interface without roles. It would be useful to ask their opinion of what we need to know and for modules to contain what we need to be taught. Low level managers actually know what our job is.

4. DISCUSSION

This paper has briefly looked at the experiences and perceptions of three cohorts of students studying on one of a number of engineering degree apprenticeships at WMG, University of Warwick. For first year students one of the key issues related to differences in what faculty members believe they are trained to do in the workplace and the knowledge and skills they actually have when they arrive in the classroom for a period of block learning. Previous studies in this area are difficult to find although there exists some literature around a perceived 'knowledge and skills expectations gap' in Biological Sciences which found a gap in student knowledge and lecturer expectations indicative of discipline-specific knowledge and knowhow (Jones et.al., 2018) although this study related to general students and pre-university knowledge.

In considering the ‘expectations and reality’ gap raised in this study, it may be postulated that such inconsistencies may be indicative of differing entry requirements for students enrolled on apprenticeship as opposed to traditional undergraduate programmes (Sole et al., 2021). In many universities, apprenticeship students do not have traditional entry qualifications, although in the case of the cohorts sampled, on the whole this is not the case. The entrance standards are similar for apprentices and traditional students within the university, although in some cases apprentices are required to possess higher grades. This means that disparities in *a priori knowledge* on admission to university should have been dealt with early in the course (Scott & Willison, 2021), meaning that problems were more likely to be indicative of different expectations of learning in the workplace

Student dissatisfaction with assessment is recorded in the literature and engineering is no exception (Oti et al., 2021); hence, it is not surprising that many students commented about how they are assessed. What is different for degree apprenticeship students is that they can be assessed on what is learned at university and in the workplace. This in itself may be problematic, apprentices on the same course may be from different employers; indeed, even those from the larger companies do not necessarily receive the same training as others working in their organisation. For this group of students, the need for carefully design assessment is of paramount importance. However, whilst the need for anonymous marking is generally accepted to be vital in promoting an equitable and fair learning environment (Giray, 2021) this may not be the case when dealing with apprenticeship students. What is needed instead is an approach to assessment and marking that is carefully designed and managed to ensure a lack of bias and high levels of integrity.

The need to nurture a culture of independent learning across the undergraduate student body, particularly in the first year of study, is recognised in the literature. This is particularly important when considering first year apprenticeship students. Research in this area is particularly spartan, with little or no previous papers considering how today’s apprentices become independent learners whilst gaining a new identity at work.

That the student participants had mostly negative views about working in groups is not unusual. Problems with groupwork amongst the traditional student body have been long discussed, although again literature pertaining to the engineering apprentice student experience is rare. Moreover, whilst moves towards blended and hybrid pedagogic approaches came to the fore during the pandemic (Petchamé et al., 2021) the impact of these approaches on first year degree apprentices remains unknown.

5. SCHOLARSHIP IN ACTION: THE DEVELOPMENT & INTRODUCTION OF EVIDENCE BASED CHANGE

This paper can necessarily only begin to touch upon the change occurring within WMG as senior management strive to induce a co-created academic and scholarly environment where student experience is prioritised and high quality learning a ‘given’.

The six themes highlighted in the findings are now briefly contextualised within the change occurring in learning and teaching.

5.1 Dualistic Education – Balancing Work and Learning:

One of the most important findings to emerge out of the study thus far relates to how little is known about the experiences of degree apprentices in general and engineering apprentices in particular. Whilst the study begins to address this gap, there is much to learn, perhaps the most important of which relates to differing expectations of what role universities and employers play in educating apprentices. The emergent findings indicate there is a clear need for continued and continual discussion between all stakeholders involved in providing apprenticeship training. Such discussion is now forming part of, and informing, transformational change; with apprentice tutors playing a key role in bridging the employer-university gap.

5.2 Assessment & Timetabling:

The main finding relating to assessment reflected problems engineering degree apprentices seem to have in developing as independent learners. To support this WMG is putting into place a ‘Student Hub’. This will be a ‘safe space’ where all aspects of the student experience can come together and students are provided with individual support and guidance in areas such as academic writing, time management as well as wellbeing support.

5.3 Pedagogy & Practice:

Reflective of ongoing advances in technology, unprecedented numbers of people now work from home. Engineering degree apprentice students find themselves in a ‘brave new world’ following the Covid19 Pandemic, it is therefore unsurprising that views about whether learning should be online, or in-person vary so much. Yet it is clear from this study is that students want autonomy to choose whether they work from home or at the campus. WMG has put in place significant measures to make hybrid learning a reality. Lectures are recorded, or pre-recorded and use of technology proactive designed into the curriculum. There are many opportunities emerging as technology advances in the field of learning and teaching, hence there is much work to do in this area, but, in actively listening to the student voice, advances are being made.

5.4 Academic Integrity:

First-year students seem to traditionally struggle with academic practice and integrity. To address this a cohort-wide module of study, professional and analytical skills has been developed specifically for the undergraduate student body. Students are able to individually access help, guidance and support in any multiple areas of academic practice in a flexible and blended manner.

5.5 Groupwork

Groupwork is part of university life. To promote group cohesion amongst undergraduates, a number of actions have been taken including providing proactive compulsory training compulsory for one cohort of students. In future, ‘working in teams’ will be covered in the student induction. Other pedagogic actions include providing training in the area of course and programme design.

Colleagues are actively encouraged to adopt constructive alignment, and quality assurance checks in place to make sure that when groupwork is used it has a solid academic grounding and justification.

5.6 Relevant Engineering Education

Student confusion in respect of the relevance of their education to their apprentice role has resulted in a more open approach to curriculum design. Students and employers both have a voice and whilst employers co-construct the degree apprenticeship programmes, plans are underway to include students in future design activities. First year students are given plenty of opportunity to ask questions about the curriculum content and context, not only during Induction but as the course unfolds. Likewise, apprentice tutors work hard with individual students to make sure that linkages between learning and work are made irrespective of whether the student is sponsored by a Small-Medium-Enterprise or multi-national engineering company.

6. CONCLUSION

This short paper represents a small part of a large, ongoing scholarship project aimed at enhancing the engineering student experience. The appointment of a Director for Student Experience and a dedicated ‘Student Experience Budget’ shows the commitment of the Department to enhancing the student learning journey. The ongoing change is beginning to pay dividends and efforts to promote a sense of belonging and identity amongst our students and staff have resulted in the emergence of a proactive and cohesive learning community. There is much work to do, but with a committed team of staff and students, working together, advances are being and will continue to be made. In conclusion, whilst the findings of this study are relevant across all undergraduate and postgraduate cohorts, the need to ‘get the first year right’ is of particular importance when it comes to engineering degree apprentices. WMG is currently undergoing a period of significant change. The team who’ve contributed to this paper are an important part of this change, working together to empower students to enable them to ‘step up to success’ both in the classroom and in the workplace.

Conference Key Areas: *Embedding Sustainability and Ethics in the Curriculum, Innovative Teaching and Learning Methods*
Keywords: *virtue ethics, ethics education, practical reflection, responsible action, project-based course*

ABSTRACT

The implementation of ethics in engineering courses often faces several intertwined problems. For example, there is widespread moral relativism, ethics is often confused with moralism on the one hand and with pro-contra discussions on the other, there are difficulties with the degree of abstraction being too high, or ethics is relativised as one method for decision-making among many others. Furthermore, in many cases, ethics is suspected of being artificially introduced into engineering.
In the context of a project-based course at a German university, we took up these challenges and developed an innovative teaching format whose focus is not on theories and methods. Instead, we implemented ethics education as a practical

exercise of reflection. Based on situations in students' project life, we engaged in open conversations addressing aspects of their practice that tend to be overlooked under conventional conditions: boundary conditions of their engineering actions, preconditions of their judgements, and criteria for justifying their decisions. Instead of reacting to problems reflexively, and thus blindly accepting them, we wanted to enable students to examine problems critically. In this way, we aimed to enable the students to adopt a (reasonable and therefore) responsible attitude toward their actions and their boundary conditions.

In our contribution, we first discuss the preconditions: the project-based four-month full-time course with an industrial partner. Second, we explain and justify our philosophical approach. Third, we describe the implementation of our approach followed by the evaluation. Finally, we conclude our findings and outline next steps.

1 INTRODUCTION

1.1 Motivation

In their paper on phronesis and the role of values, Frigo et al. (2021) highlighted the need for teaching ethics in engineering and discussed a potential application. However, the responsibility that engineers bear in their professional activities has not been reflected widely as part of engineering education, especially at German Universities (Frigo et al. 2021). The central role of engineers in finding technological solutions to fundamental societal problems (Frigo et al. 2021) thus leads to the necessity of teaching ethics in engineering education. Courses that are more practically oriented can provide a particular purposeful opportunity (Frigo et al. 2021). Based on the preliminary considerations of Frigo et. al. (2021), this practice paper develops and implements a detailed concept for teaching ethics in engineering education at a German university and reflects on its evolution over two years.

1.2 Our mission

Within the framework of a German excellence promotion program, we pursue the goal of building reflective competence among students in ethical and social issues. The overarching approach chosen can be described as teaching “ethical literacy” and is characterized by teaching ethical-reflective competence instead of principles and theories. For this purpose, our interdisciplinary team led by philosophers offer a variety of services, including online courses, co-teaching events, and challenges to realize the above-mentioned goal. The course presented in this article is part of this offering.

1.3 The project-based engineering course

In the course IP - Integrated Product Development in which we are implementing our pilot project, a selection of master’s students from the fields of mechanical engineering, industrial engineering, and mechatronics work in teams through a 4-month product development process from strategic foresight to prototype construction. The problem definition for the development project is provided by an industry partner. During the project the students independently develop product profiles, alternative solutions, and prototypes, which they present to the industry partner and invited guests from research and industry at a final event (Albers et al. 2018). As the main stakeholder for the solutions developed by the students, the industry partner is pivotal to the practical learning environment.

The coordination of the development process and the methodological coaching of the students is carried out by scientific staff of the IPEK - Institute of Product Engineering, who are themselves mechanical engineers. Decisions as well as feedback on the intermediate results takes place through the industry partner at multiple milestones. Between these milestones the students independently decide how they spend their time and balance efforts. The course can be associated with challenge-based and project-based learning methods (c.f. Membrillo-Hernández et al. 2019). Fundamental to the course is the understanding of product development according to the Karlsruhe School of Product Development (KaSPro) specifically in relation to demand- and benefit-driven innovation (Albers, Düser and Burkhardt 2006).

Due to the students' freedom of choice, its implications, and the courses’ nature as preparatory for the students' entry into work (as part of the master’s degree), the course offers a well-suited opportunity for our mission and the obligation to address responsibility in engineering education. While there have already been preliminary conceptual considerations, the development of a consistent teaching concept and its implementation remained open. Therefore, this contribution justifies and proposes a detailed concept for teaching ethics as a practice while acknowledging the complexity of engineering education. Moreover, the concept is implemented and evaluated with two cohorts in the winter terms 2021/22 and 2022/23.

2 TEACHING ETHICS AS A PRACTICAL EXERCISE IN REFLECTION

In both teaching and being taught theoretical content, we are accustomed to viewing this content as retrievable pieces of knowledge. Examples include the fundamentals of engineering mechanics, mathematical methods, functional principles of machine elements and many more. In engineering courses, we teach many such things, which are undeniably important. Alongside this kind of knowledge, we also teach and learn methods which are instructions or procedures that help us to contribute to a solution of a given (technical) problem under certain circumstances. A good engineer is characterised not least by the fact that they are able to choose the most appropriate method for the problem from their arsenal of methods. In this way an engineer demonstrates the competence to understand the problem as well as the function and mode of action of the chosen method to be able to apply it purposefully. The interaction of theoretical knowledge, knowledge of methods, and the understanding of problems makes engineering a lively activity—especially when engineers become creative and have to work out new ways of solving unprecedented problems. This lively activity can be called "practical skills".

Whoever wants to teach knowledge, methods, or even practical skills is faced with the question of the best way to do this. Under certain circumstances, one must also ask oneself the definition of "best" here. Of course, we also had to ask ourselves what it could mean to teach what we wanted to teach.

We knew we wanted to enable students to act in a responsible way. Assuming what it means to act responsibly would be a kind of theoretical knowledge, we could have taught our students a theory of responsibility and tested this knowledge in an exam. While this might be possible, the concept of responsible action does not describe knowledge about the world or about how people are but addresses their actions. Having an idea of what it means to act responsibly enables one to identify and evaluate one's own actions or those of others as such actions accordingly. But then one does not have theoretical knowledge, but a norm for a way of acting. And with norms, you have to justify why they should do in this way. To understand responsibility as a kind of theoretical knowledge seems at least problematic.

What would it mean instead to understand responsible action as a method? If so, we could have told students to follow a procedure and their actions would henceforth be responsible. But we did not want to teach one method among other methods, or even the most important method of all other methods. We wanted students to be able to make responsible use of their arsenal of methods in case of doubt. The ability that we wanted to make accessible to our students concerns the *how* of their actions–not just the *what*–and it seemed to us that whatever was connected to that ability lay to be beyond the choice of method. Because this ability is neither theoretical knowledge nor a method, but is expressed in people's actions, we ultimately had to understand it as a kind of practical skill–namely the practical skill to act responsibly. Approaching our concept of responsibility in this way raised another question: how must we understand our mission based on this understanding of responsibility so that we can seek options for its realisation that do justice to the matter of responsibility?

However as often happens in philosophical practice, the questions are initially unsettling: instead of providing support and finally a solution, they seem unnecessarily complicated and endless. Couldn't we have simply defined responsibility somehow and then taught this definition to the students? But wouldn't responsibility then have remained merely a piece of theoretical knowledge again instead of becoming a practical skill? And would it have been responsible at all to simply define the concept of responsibility in that way or to adopt it from others without reflection? What are the criteria for us to act appropriately in each case?

Therefore, the question of how we would understand responsibility not only affected what we wanted to teach, but also our own actions. As we have said, the easiest approach would have been to simply presuppose a given understanding of responsibility and tell the students how to act in the future. Then we would have solved the problem that we need a concept of responsibility. But we would have left the context unconsidered and thus already accepted the conditions under which the perceived problem appears as a problem. Consequently, just because the problem-solving mode is possible does not mean it is appropriate.

When we are responsible for teaching others what it means to act responsibly and why they should act that way, then we firstly have to be able to justify why this is a good concept of responsibility. And secondly, if we don't want to get tangled up in contradictions, we must do justice to our responsibility both in the rationale for it and in the way we want to convey it. This means that whatever concept of responsibility we choose, it reflects on us and on our actions. When we think about how to teach responsibility, we have to look at what we do while thinking about it.

What did we do? First, we wanted to gain a proper understanding of it. We did not accept the supposedly obvious problem and set out to find a solution for it. We refused, in this context, to presuppose an arbitrary understanding of responsibility or to recognise an understanding of responsibility merely because it comes from a potential or supposed authority. Secondly, we did all this with a view to asking how we must act to do justice to the matter. Thus, thirdly, we have understood and reflected on ourselves as the cause of our actions. What would it mean if that were already a form of responsible action? According to this view, a person acts responsibly who relates to their own actions in a certain way: They ask themselves *what* they do, *why* they do it and *how* they do it (in what way and under what conditions). Since they understand themselves as the cause of their actions, they also understand that they can relate to them in reflecting on these issues. This means that they can and must also ask themselves whether they should do what they do or what they should do for what reasons.

We wanted to enable the students to look at their own actions in this way as well. They were to be enabled to make the presuppositions of their own actions transparent to themselves. We considered that if the students could learn to do this, they would in future act less automatically in the way they have done it in the past, or do what they do less arbitrarily, or not act merely out of obedience.

But with this it was also clear: if we want to give students the opportunity to make decisions and to act accordingly in a responsible way or more responsibly than they may have done in the past, then we cannot treat them like automatons that one feeds with input. Instead, we must see them as acting subjects who ought to be able to arrive at independent judgements, and whom we must therefore also allow to contradict us. Not in an arbitrary way, of course, but we would be good teachers if we were exemplary in what we try to teach. In other words: teaching in this respect and in our context would have to be a practical exercise in reflection for *both* sides—for the teachers as well as for the learners. But since no one can be forced to reflect, there would also be no guarantee that the impartation would succeed. The possibility of

failure still lies in the nature of things. It is in our hands to provide the possibilities to be able to relate to one's own actions in a reflective way. But as with any other opportunities, there is always the option of refusing this offer. Since taking responsibility is something that can only be done by the actor, we have no choice but to rely on the voluntary understanding and acceptance of the students.
With this, we have finally reflected on one last aspect of responsibility as it arises in our context: the scope and limits of our responsibility. In conclusion, when talking to the students about responsible action, we would have to enable them to:

- understand themselves as the cause of their actions,
- therefore ask themselves what they do, how they do it and why they do it,
- therefore reflect on what the specific conditions of their actions are and what, against this background, falls reasonably within their scope of action for which they are responsible, and
- finally be able to reflect on whether they should do something—and what they should do as well as why.

At least here, responsible action thus shows itself as a kind of justice: those who act responsibly (under conditions) try to do justice to certain aspects of their actions, especially being the cause of their actions. So, what we would have to teach as a practical skill would be a particular attitude towards one's own doing. And because this attitude positions one's own actions under a principle—in our case under the principle of responsibility—it can be referred to as an "ethos". In our understanding responsibility starts here. But whether it also ends here is another question.

3 RESULTS

3.1 Implementation

As we have seen, the essential part of our teaching should be to enable students to develop an attitude towards one's own doing. The core of our teaching must therefore be to offer them opportunities in which they can relate to themselves and practice reflective competence. To enable this reflection, we have set ourselves three goals (cf. Fig. 1): 1) we would need to "open doors" to a new attitude for the students; 2) we would have to enable students to "open doors" to reflection for themselves; and 3) we would have to show the students connections between their attitude and the work they do on their project.
We call the overall concept "ethical accompanying reflection". The concept consists of four distinct but connected components: a 90-minute ethics lecture, a 120-minute ethics workshop, a series of reflection sessions and a lecture series. The first three components were delivered by trained philosophers, mentors from the Institute of Philosophy. The lecture series component was realized by inviting "practitioners" from the industry.
The **ethics lecture** represents the students' first systematic encounter with questions of ethical responsibility within the framework of the course. It is structured more traditionally as a lecture and is intended to convey the relevance of dealing with this topic in this framework. We expect the ethics lecture to contribute to goals 1 and 3 we mentioned. In the current version of the lecture, the necessity to deal with one's own responsibility is derived and justified from the self-image of engineering practice: since they experience and understand themselves as acting and shaping, the necessity of responsibility can also be addressed based on the experience of this freedom now.
The **ethics workshop** is also a plenary event and is intended to create a bridge between the ethics lecture and the reflection sessions. We regarded the workshop as

serving our goals 1 and 2. Accordingly, it differs from the ethics lecture in that the students should already be actively involved in discussions–in accordance with our approach–not with the aim of developing solutions to problems, but rather in such a way that their answers can themselves be made the subject of joint analysis and discussion. In this way, the workshop interrogates the students' "natural" judgements and addresses the basis for their justification. In the current version, we devote most of the workshop to discussing a trade-off example: confronted with the question of how the AI of an autonomously driving car should "decide" in a certain dangerous situation, we divide the students into teams. They are asked to discuss the basis on which they would make and justify their judgement under the guidance of their philosophy mentor. The results of the team discussions are shared with everyone in the final plenary again. The aim of the exercise was not to arrive at a definitive judgement on a seemingly harmless example, which presumably everyone would have an opinion about, but to ask what the students presuppose for their judgement in each case, and in turn to make this presupposition the object of consideration.

As the most appropriate way to engage with the students and thereby create the space for reflection, we decided to have multiple small group meetings with the teams, called **reflection sessions**. They form the core of our accompanying reflection: each student team is assigned a philosophy mentor who meets with the team for four 90-minute sessions over a period of two months. The themes of these sessions are not determined by the philosophy mentors, and no pre-determined learning objective is issued for any of the sessions. In these sessions, it is very important that the philosophy mentors engage with the students and react to the situation they are in. Of course, the discussion is about the status of the development projects themselves. But in this discussion, aspects of responsible action are worked out–not following a theory, but through the philosophy mentors engaging with the situation in a new way, i.e., with the object itself. Here we ask which criteria the students have used for problem identification and innovation potential, and why these criteria were used instead of others, for example. We ask about their reasons for ultimately choosing one product idea for implementation and why these are good reasons. We ask about the fundamental values that they are acting on in the project and why they think that they should do so. We further ask what they see themselves as responsible for and what they don't, as well as the reasons for that. In this way, the students are confronted with aspects of their judgements and actions that are taken for granted and otherwise rather non-objective for them. However, this does not happen artificially and with external standards; rather, it emerges from the project situation and is based on the criteria and standards expressed by the students themselves. In this way, we enable ourselves to discuss not just what should be done, how it should be done, and for what reasons, but also where the responsibilities and the limits of our own responsibility lie. The reflection sessions are therefore suited to each of our three goals.

As a final component, we organized a **lecture series** as a complementary format. In this series, we invited five guest speakers to talk about situations in their professional practice in which they were confronted with questions of responsibility according to their own assessment and the challenges their faced. The aim was not to tell success stories. Rather, these presentations were intended to demonstrate the many different levels on which such questions of responsibility can arise, which cannot be dealt with using a standard procedure. To ensure a certain uniform structure in the lectures and an orientation towards our need for knowledge, we drafted a catalogue of guiding questions. In addition, we held preliminary talks with all the speakers to agree on the direction of the presentation and discuss a first draft. The lectures themselves did not refer to each other, but we organized them in a way that the levels of reflection changed from lecture to lecture. In our view, this was well-suited to helping achieve goals 1 and 3.

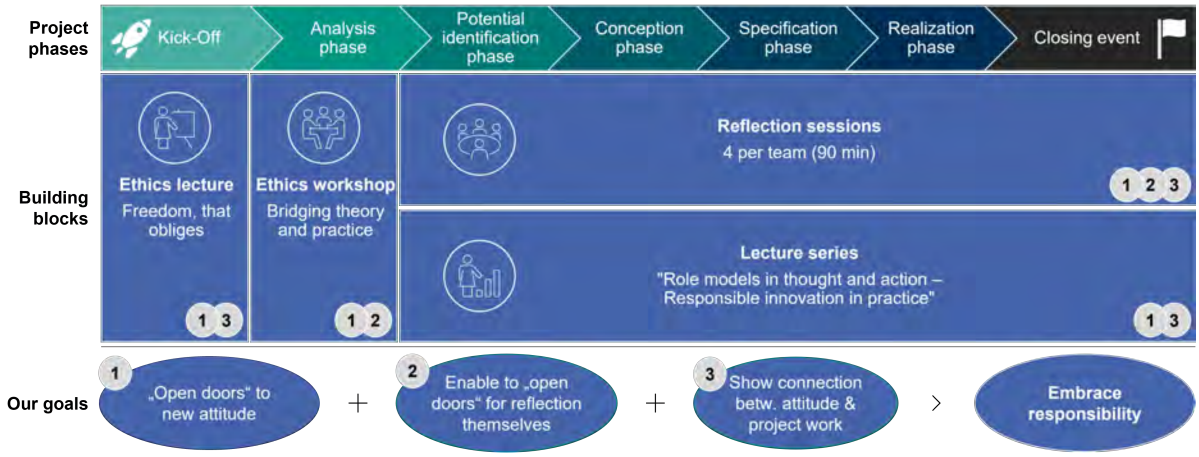

Fig. 1: Project phases of the course and implementation of the teaching approach

3.2 Evaluation and Discussion

Of course, we asked ourselves about possibilities for determining whether our accompanying reflection has an impact and, if so, what kind.

A possible impact can be analytically differentiated according to the "places" in which it finds expression. It would be desirable to look for an impact in the results of the students' work. We do not know any method to determine this, since it is impossible to determine the results that the students would have arrived at without the accompanying reflection. Since we do not primarily want to impart knowledge, but rather to enable an attitude, which only shows itself in practice, one would have to ascertain the status of the students' attitudes beforehand. And even so, it is uncertain whether they subsequently act due to an "ethos" or only display a socially desirable behaviour. A possible approach is to ask which aspects of their decisions the students themselves would attribute to the accompanying reflection. However, such an effect would only be an indirect phenomenon, which could also only be determined unreliably by discourse, even if the discursive discussion would be interesting.

This discursive element does, however, point to a second "place" where we can evaluate a possible impact, namely the reactions to and judgements about the accompanying reflection by the people involved. For this, we perceived various evaluation possibilities, some of which were quite elaborate (cf. Table 1).

Table 1. Applied evaluation methods.

	Students	Mentors	Externals
Cohort 1	Anonymous questionnaire	Interim reflection meeting with engineering mentors and philosophy mentors	Sociological accompanying study
		Follow-up meetings with engineering mentors and philosophy mentors	
Cohort 2	Anonymous questionnaire	Interim reflection meeting with philosophy mentors	/
		Follow-up meetings with engineering mentors and philosophy mentors	

		Documentation assignment for philosophy mentors	

In both cohorts, we were not able to derive any tangible improvements to the course from the questionnaire, but we were able to confirm the fundamentally positive reception by the students. However, participation in the survey was limited to 40 percent in each cohort. In addition, students' responses were very diverse in individual aspects of the course, but students did not make use of the opportunity to give their reasons. For us, it therefore remains unclear according to which criteria the students judged and whether these are appropriate. Certainly, the fact that the reasons for their responses were mostly omitted that the students did not consider the possibility for a discursive discussion with us to be necessary–whatever their reasons may have been.
The interim reflection meetings and follow-up meetings with the mentors of the first cohort were rather unsystematic and most closely resembled an exchange of experience. A shared finding was the fact that the students had difficulties understanding the purpose of the accompanying reflection and had expectations that we could not possibly fulfil because they did not correspond to our mandate. We therefore brought to the second cohort the insight of needing to manage expectations better and we clearly stated what our mandate is not in as many places as possible. This insight flowed into the conceptual redesign of the ethics lecture and the ethics workshop as well, both of which aim now to better reflect what constitutes the core of the accompanying reflection in their content and procedure.
For the first cohort, we also accepted the services of sociological accompanying studies. A research team from the university was commissioned to use a qualitative study to investigate the effects and impacts of our teaching offer for the students and to develop possible suggestions for improvement. Data was collected through participant observations of our teaching practice, semi-structured interviews with students and philosophy mentors, as well as text analyses of the milestone presentations. The 29-page study, which is not publicly available, concluded overall and in principle that, on the one hand, "the integration of ethical and responsibility-related reflective content in the course [...] was valuable according to all participating students, engineering and philosophy mentors" (Hausstein 2022). It also stated that our project required a considerable amount of human and temporal resources, but with external conditions being beyond our control, was not always able to meet this requirement. On the other hand, several other results showed that this study was based on a different understanding of our role than what we discussed in section 2 above. The study thus has only limited usefulness for us. If it were to be repeated, we would have to engage with our colleagues in a much greater effort to reach a common understanding of what we aspire to.
In contrast, a real novelty was introduced with the documentation of the reflection sessions by the philosophy mentors in the second cohort. We of course asked ourselves whether we had given ourselves a meaningful work assignment with this format in the first place, whether the considered approach made sense, and what we might have to change in the objectives. Therefore, the documentation by the philosophy mentors is a kind of reflective self-evaluation, which should have the side effect of individual reflective follow-up by the respective mentors. In six questions, each with sub-questions, the documentation asks, among other things, about the topics discussed, the ethical issues discussed, the particularly noteworthy interventions on the part of the students in terms of content and performance, and the approaches used by the mentors, as well as what the mentors would do differently in

retrospect to their own approach. As a result, we have a large amount of data that both allows for a comparison between the individual teams for each session and would make a possible development over all reflection sessions visible for each team (which is currently being evaluated for the second cohort). Of course, the same applies to the philosophy mentors' assessments of their own approach.

4 SUMMARY AND ACKNOWLEDGMENTS

We have shown that our entire teaching concept is designed to provide opportunities for reflection on one’s own practice of judgement and its presuppositions in order to potentially adopt a new attitude towards one’s own decisions and their foundations. Our primary goal is not to impart knowledge that can be tested.

The evaluations completed thus far and those currently ongoing indicated, that we set high aspirations for ourselves and require a high degree of willingness of the students to engage with us as well as to spend enough time engaging with the topic of responsible action in addition to everything else they must do for their projects. This willingness is not always present or evident. Some students tend to dogmatically determine for themselves and everyone else what is right and what is wrong and use rhetorical persuasion to get their way. These students do not seem to be interested in conversation. But they are the same students who cause unproductive conflicts in other team contexts in the project. Consequently, the reflection sessions then help other team members to see the real problem and its logical causes. They can then limit such destructive actors with reference to the common team purpose–again encouraged by the reflection sessions. In addition, there are those students whose thinking–for whatever reason–cannot break out of the problem-solving mode during the mentoring period, and who thus block their path to reflection. Our outreach is most promising with those students who are open to learning something new. They curiously accept our offer to try something different from what they are used to and to take a distanced view of their own presuppositions and supposedly self-evident facts. All students demonstrate that they make value judgements and have an idea of what is right and wrong. But not all of them are therefore ready to talk about it. Not even when they make value judgements in a professional context and their attention is drawn to it. But since we are always dealing with teams and groups, the actual addressees of such disputes are then the other participants, even if they are only observing. In all this, we must concede that with the at least perceived high pressure to succeed in their project, some students simply do not have the necessary time to acquire such a self-critical attitude.

As mentioned above, it is difficult or impossible to reliably demonstrate a direct impact of the accompanying reflection in the final products of the students’ projects. And it is equally impossible to verify a virtuous attitude. However, since we have the discursive option at our disposal, through which we can indirectly determine whether someone is performing in a responsible way, from our point of view the next step is to find an answer to the question of which approaches are suitable for obtaining feedback from students in which they can prove themselves to be the mature, responsible persons we are trying to address them as.

However, our own standards also show that we ourselves must not succumb to the pressure of problem-solving thinking. We must set aside our own reflexes and be reflective in our exchange with students and in dealing with their problems and our own. Admittedly, in what we are trying to teach, there is no guarantee that the teaching will succeed. But the least we have to do is to measure our own actions against these common standards of responsible action and assess whether we are living up to them.

In turn, this seems to us to be a central prerequisite for a possible transfer of our attempt to other contexts. And this insight is as old as the philosophical doctrine of virtue itself: whoever wants to convey a virtuous attitude must act as a role model in this matter. They must demonstrate in practice what it means to act virtuously, and they must provide the framework conditions in which it is possible to learn to act virtuously. In our case, these conditions comprise the hopefully exemplary behaviour of the philosophy mentors in the reflection sessions, the reports in the series of lectures by the practitioners, and, we hope, the overall conception of our accompanying reflection. Whether our ethics lecture, ethics workshop, and our style of reflection sessions make sense in other contexts depends on what exactly is to be taught. In our opinion it makes sense if you want to create an opportunity to show what responsible action can mean and if you understand responsibility in the way we have made explicit in section 2. However, in our opinion the internal reflective consistency of content and practice is what matters in any case.

ABSTRACT

Project-based learning bridges the gap between theoretical training and practical applications. The motivation of students to participate is increased especially by working out real-life problems. To provide this kind of practical learning experience, we are establishing a repair project for broken, otherwise discarded, lab equipment. It will not only help to reduce waste and save money by repairing research equipment, but will also encourage interdisciplinary collaboration and innovation. Providing a space to learn about the underlying functional properties of various often highly specialized lab instruments, students identify malfunctions, deepen understanding of vulnerable designs, and discuss and perform strategies for repairing them under guidance, while collecting credit points. Through gaining a deep understanding of how these instruments work, students may even invent new strategies to realize similar tasks or add new features. This project builds on the findings from a 2021 pilot study. We discovered that by offering a repair project, students were able to gain a deeper understanding of theoretical concepts, improve their self-confidence as well as their motivation in learning, and increase their awareness of sustainable design. In the following, we are presenting the transformation of the pilot study into a current course concept. With weekly mini-evaluations we are monitoring students' learning success towards their learning goals and share the results.

1 INTRODUCTION

1.1 Motivation

"Addressing the complexity of sustainability requires innovative practices for teaching and learning, leading to new methodologies that aim to develop the broad sets of competencies required from the students." (Kunrath and Beliatis 2022)

The 12th goal of the Global Goals Agenda for Sustainable Development ("United Nations Development Programme" n.d.) demands responsible consumption and production. In this context, in addition to an improved process cycle and the reuse of components, the repair and preservation of existing equipment is an essential sustainability goal. These goals are gradually being enshrined in EU legislation. For this reason, the European Commission presented a proposal on the "Right to Repair" - consumers should be able to have defective "consumer goods", such as household appliances or home electronics, repaired more easily (European Commission 2023). These goals continue at the state level and are promoted in the German federal states. Technische Universität Berlin is also striving to integrate sustainability goals, ethics, and diversity into its curriculum. Since studies show that increasing awareness of sustainability leads to an increased integration into higher education (Sammalisto and Lindhqvist 2008), interdisciplinary projects may serve as a multiplier.

Similar to production-oriented and recycling-oriented designs, a shift towards repair- and maintenance-oriented designs for appliances is necessary in the medium term. Students must be taught the skills necessary to adapt to this change in the future work environment. Some of these design approaches are already part of the theoretical training, but they need to be deepened in practice. Just as the skills required for creating a design suitable for production are best acquired by gaining hands-on experience in manufacturing the components one has designed, developing a design that is suitable for repair also requires practical experimentation, including learning from negative examples.

In a preliminary teaching survey about students' needs and course topic preferences, sustainability was ranked second highest, surpassed only by the inclusion of current research topics. The big majority indicated the development of hard skills being their main learning goal, with a preference of learning technical content through hands-on formats (compare results 3.2). Since the devices to be repaired are intended for scientific use and the project aims at an intensive exchange between students and device users to gain a deep understanding of the functional principles, the presented project can fulfil many of these wishes and also combine sustainability with insights into current research topics in an interdisciplinary manner. The survey results were confirmed during the first iteration of the repair project, where it was integrated as the practice part of an already existing engineering course. 75% of students chose the repair project from a selection of six various hands-on projects.

In addition to the development of skills for the creation of repair-oriented designs and equipment, this teaching method offers the opportunity to further deepen theoretical and practical knowledge, to bring existing knowledge into the application and to support interdisciplinary exchange. In order to achieve these learning objectives efficiently, didactic methods and safety principles are required. Many common factors such as lack of goal clarity, low motivation, disorganized thinking, or mood swings can affect academic performance. Goal setting in particular plays an important role in social-cognitive learning models of academic achievement. According to psychological models, successful performance is associated with positive feedback loops between self-efficacy and goal commitment. When a student achieves a goal successfully, self-efficacy increases, which in turn increases commitment to the goal and mobilizes self-regulation of cognitive and motivational resources to facilitate further achievement (Morisano et al. 2010). For this reason, individual learning goals are developed in collaboration with mentors at the beginning of the project. These are continuously queried and reflected upon in the form of control loops.

1.2 Repairing: A way to strengthen sustainability learning goals?

Repair practices represent technical skills that allow designers to gain competencies in circular design (Terzioğlu and Wever 2021). Initially, students gain hands-on experience in troubleshooting and problem-solving, which effectively strengthens their critical thinking abilities. Repairing equipment also requires an understanding of the operating principles of the equipment, which encourages students to apply acquired theoretical knowledge to practical challenges. In addition, repairing scientific equipment promotes a deeper understanding of the importance of maintenance and sustainability in mechanical engineering. Students learn how to extend the life of equipment and reduce the environmental impact of industry by repairing and reusing equipment rather than replacing it. This is in line with the growing demand for sustainability in engineering and allows students to contribute to this important issue while developing their skills. Finally, repairing scientific equipment gives students a sense of accomplishment and pride in their work. Successfully repairing a piece of equipment provides a tangible result of their efforts and boosts their confidence and motivation to continue learning and growing in their field.

2 METHODOLOGY

2.1 Project organization procedure and didactic approach
